TO OUR READERS.

— x —

PRAISE totally unexpected and disinterested is the superlative of commendation. The celebrated beautiful Duchess of Devonshire said, "No compliment ever equalled that of the coalheaver who asked me to let him light his pipe by my eyes." One of our Editors travelling in Wales saw a cottager reading "our Journal" as she sat in the sunshine before her door, and who said in answer to a query, "We could not get on without this Journal." Nor is the aid we are able to afford confined to the British Isles, for we have letters asking for information from the Cape of Good Hope and from the Himalayas, and the day we wrote these words we received the following letter from Canada:—

"Recent articles in the Journal show that this Ontario of ours is not such a far-off province as to be beyond the reach of your interest and influence, so I have sent you by this mail the prize list and regulations for our horticultural shows here, thinking it might interest you to know a little of what is being done here in that direction. For my own part, I know, I look forward month by month to the arrival of my "COTTAGE GARDENER," for it speaks to me of home and all I left behind me there."

Such testimonies are most gratifying, and we again thank our contributors for enabling us to say without self-laudation that we know that the commendations are merited and that they will continue to be deserved.

ARBORESCULE GARDEN AND SWANERY.

From observations taken near London during forty-three years, the average day temperature of the week is 41.5°; and its night temperature 29.6°.

A NEW YEAR'S WELCOME.

"Welcome ever smiles,
Though Farewell goes out sighing;
For time is like a fashionable host,
That slightly shakes his parting guests by the hand,
But with his arms out-stretched, as he would fly,
Grasps in the corner."

SO saith Shakespeare. We learn, therefore, that fashionable hosts were about the same three hundred years ago as now. The guest has told his tale and acted his part, contributed to the amusement of others, and he may go; or he has failed, and outstayed his welcome. In any case he may go; his time is over, and his presence not needed. The old year is the old guest to us; we have shaken hands with him, we gardeners, not very cordially,

for he has not been a very good friend—too cold for too long a time at the beginning; half his time over nearly before he was warm and genial. May gone before spring came. Then he warmed indeed, and such heat! so scorching, so killing to flowers, that his July and August were terrible. With floods and storms he ended. He is gone, may the next year be better. We stretch out our hands to 1877 and bid him welcome.

Next to the farmer, how much the gardener depends upon the weather! The farmer cannot indeed spread a tent over his hayfield, but the gardener can protect his flowers; yet the gardener has not only to fight against bad soil, but bad seasons as well. He can, in fact, overcome the former, but who can overcome the troubles the latter bring? Yet who would give up gardening because of its difficulties? Scotchmen are said to be superior gardeners, because they come from a country where they have more difficulties to contend against than their brethren in England. Besides, Englishmen like to fight against odds. "Hard fighting, gentlemen, to-day," said an English general, when the foe fought hard and the cause seemed doubtful; but he added, with a true English disregard for odds, "let them see who can fight the longest."

'Tis wonderful how fond of overcoming difficulties we are. Last Crystal Palace Pigeon Show I heard one gentleman drawing the attention of another to a certain class of birds, saying, "Those are good, are they not?" Mark the answer given: "Yes, pretty enough; but too easy to breed." The English spirit spoke out then. So I would say, Gardeners, in welcoming in the present year, not knowing what you may have to face, be determined to succeed. Read and work, study in the dark long winter evenings, and by day watch and work; don't be content, young men, with the knowledge you have acquired. Gardening is not like Chinese painting; there is always something new to learn, and some progress is to be made, some region unexplored, and profitable. Not like the Arctic regions desolate and dreary, but pleasant and cheery. There is something very fascinating and attaching in gardening. Collectors notoriously take up and drop their hobbies: now coins, then stamps, then china, but these are human arts, and often and very soon tire,

because soon exhausted; but who that once loved a garden ever tired of it? Who delights most in the gardens in the London parks? People bred in the country, and who had gardens, but who being in London cannot have any: hence they adopt the gardens the State supplies as their own, and enjoy them, not quite as if their own, but still how much they enjoy them.

One old Roman story—that of Cincinnatus refusing to leave his farm for great civic honours—is well known; another is not so well known. It is this: The Emperor Dioclesian after he had resigned the purple retired to Dalmatia, and his successor tried to induce him to return to the cares of state, but without avail. His answer was, "If only you could see the Cabbage which I have planted with my own hands you would not ask me to return." True, Cabbages do not indicate what we should call high-class gardening; but more, I dare say, remained unmentioned. One garden amateur takes to vegetables, another to some fruit—Grapes, or Pears, or Apples; another to some flower or arrangement of colours; while the artisan of the north bestows loving pains on Gooseberries, or (oh! "D." of Deal, though of Deal no longer, yet thine is not unfair dealing) to Auriculas. There is room abundant for all tastes, all choices at the great banquet of nature. A garden is the greatest recreation of the mind; and says one, "My ideal of as perfect a life as is attainable in this world would be a life of a modest and serene man of letters, loving and loved; within surrounded by his books, without encompassed by his Roses." Truly a charming ideal. And perhaps because his study looked into a conservatory at his last residence was one reason why Macaulay, after describing his home, wrote, "I do enjoy this invalid life extremely." And in truth I cannot imagine any man more miserable than one obliged to live in the country, yet with no love of the country. There is a sweet and gracious presence of a noble lady of the highest rank upon which I sometimes look, and always with respect, but with greater respect and reverence now that I know that she goes up to the London season as late as possible, and returns to her noble country home as soon as possible, in order to enjoy her flowers and country duties and pleasures. It is this living in the country among tenants large and small—the great-acred farmer with humble cottager—that binds rich and poor together in a loving bond in this England of ours. Mr. Gladstone once boasted in an eloquent speech of his that "in foreign countries a piece of ground laid out with a view to producing a picturesque effect was always called an English garden;" and no compliment to English tastes or to English gardeners could be greater.

I have sometimes wondered that better gardens are not, as a rule, to be found attached to farmhouse. Good orchards often, but good gardens seldom. It seems that this is also the case in America, for I read in a New York periodical—"How seldom do you see a good garden attached to a farm, yet no one has the facilities in this respect commanded by the farmer. With abundance of land, fresh stable manure with which to make a hotbed of any extent, choice of soil and exposure, steam imple-

ments always at hand, and odd minutes that cannot be better turned to account than in making home beautiful; he need play second fiddle to no one as a horticulturist. A garden adds immensely both to the charm and the value of a country place. 'A love of a cottage' embowered in trees and encompassed with fruits, flowers, and vegetables, is the ideal home about which merchant princes jammured in the city are evermore dreaming. This dream every farmer can convert into a reality. Taking the purely utilitarian view of the subject, a well-kept garden is the most remunerative part of an estate. Leaving the flowers out of account—though the ladies will not fail to appreciate these—the fruits and vegetables will be a rich source of family supply, comfort, and health." Now all this, true no doubt of America, is true also of England. I believe it is customary to say "farmers are bad gardeners," and there is a prejudice on this subject, just as there used to be in the old-fashioned farmer against the use of machinery. For some years every ordinary farmer expected and prophesied that he who used machinery would be certain to become a bankrupt. The prejudice against gardening neatness and goodness at a farm will also soon pass away, and then we may expect the farmers of England to be proud of and show gardens superior to any other class in the country. Professional men delight in their gardens, so do tradesmen, so do artisans and the higher class of cottagers.

The subject of hardy fruits is occupying much attention in England. One writer suggests that all railway cuttings should be planted with Apple trees, and calls attention to the subject in a pamphlet entitled "Ten thousand Miles of Apple Trees." The title is sensational, but the plan might be carried out, and vast quantities of land be utilised; and I should hardly think traffic would be interfered with, unless a train full of schoolboys overpowered the guard, held a pistol to the head of the engine-driver and bribed the stoker, and then made a raid upon the trees on their way to school after their summer holidays. We are told by travellers that in Java the birth of every child is celebrated by planting a fruit tree, which is carefully tended as the record of the age of the child whose birth it registers. This wise regard for the future deserves imitation. There is another plan I should like to see adopted—that is, that landlords of cottage property in the country should plant a couple at least of good Apple trees in each cottage garden. These would come in useful to a family, and a well-stocked garden helps to keep the tenants in the country, much to their true interests and the benefit of the farmer. It is a curse to a country when its peasantry rush into the large towns. Emigration of the labouring class has been carried far enough, and when a shipload of poor creatures arrives in Australia, instead of being welcomed they are received with hisses and groans and told to go back to England. How discouraging such a reception must be to poor English husbands with their wives and children, who, having escaped the perils of a three-months voyage, are looking forward to a plentiful and comfortable home in a foreign land.

A good hint is given by Mr. Holgate which I would recommend to the attention of workhouse masters in rural districts. He says, "I think a good opening for boys might be found if the master would take an elder boy under his charge and teach him some of the more advanced points of garden work, such as taking cuttings, budding Roses, planting and potting, &c. This has been done in one school with such good effect "that boys," says Mr. Holgate, "so taught are snatched up immediately by the neighbouring families. School gardens for vegetables and flowers might also be arranged. All this has been done in a union workhouse in which I have been interested for many years, and in addition the boys have gardens of their own; and the master, himself a very successful prizetaker both in flowers and vegetables, gives prizes to the boys for the best-kept garden, an example which might be followed with advantage. In the same workhouse the aged people's wards are full of flowers, and they have charge of some bedding plants in the winter, while their court is bright during summer with Geraniums, Hollyhocks, Dahlias, &c. All this adds an interest to their lives, and, like the bright pictures put by the matron on their walls, makes them a great deal happier. The monotonous regularity of a workhouse life is to all strangely depressing, and nothing tends so much to remove this weariness as a plentiful supply of flowers."

Before leaving horticultural subjects one word about our Apple and Pear elections. These will, I hope, go forward, and will be a means to a very desirable end—viz., clearing from our gardens and orchards bad and half-bad varieties.

I must now turn to that other department of "our Journal" which takes in birds of all kinds, but chiefly the fowl and the pigeon, and excludes not the rabbit, while it gives great prominence to the honey bee. Prize poultry seems to be esteemed more than ever. Where ten men wished to keep them ten years ago a hundred men do now. Those who prophesied that the love of keeping these birds would cease, and who called it a mania—a rage, have proved to be false prophets. A spilling bee may be a mania, but not poultry. Then when a man moves near London or into a town, and has to give up fowls, he only goes into the kindred fancy, that of pigeons. He only transfers his pets to the other part of the show. Where people cannot keep living things of value, how they will take up with living things of no value! A pet they must have. This is well illustrated by an extract which follows, from the visit recently paid of an Englishman to a Spanish prison. "As I passed" says he, "into the last court of the prison I had a view of the prison pets. Here a poor lad from his lone charcoal-cutting hut in the wild sierra, a child of ten years old, had brought his father a mountain fox, which strained at the leash and darted about in all directions. Here a fearful-faced dark-eyed girl had brought a tiny cageful of birds; others had brought other pets. A little cluster of the men were kneeling down, I observed, in a corner of the courtyard; and when I peered over their shoulders to see what was the attraction, to my surprise they were feeding two tiny sparrows, which, they told me, had fallen out of their nest into the courtyard and were now the pets of the prison." So have I seen in an English hospital a poor consumptive lad whose greatest delight was rearing a nest of young linnets, and he was as proud of them as possible, pointing out to me which he considered the best, and how this or that delicate one had improved under his care.

I think the advantage of a hobby for the artisan class, now that their hours of labour are shorter, is even greater than in former days, and would prove a counter-attraction to the public house and the skittle alley; and the more energetic a man is, the more he needs some outlet for his energy which will occupy time and thought. An engine wants a safety-valve, and without a resource of some kind a man is apt to become the victim of too much tobacco, or of something more hurtful. Hence I am very glad to see prizes offered at our large shows for the less expensive classes of pigeons, as, for instance, for flying tumblers. This class at Bristol was well filled. So also I advocate everywhere a class for mealy pouters; their price is within the means of artisans. The mealy, well barred and coloured, is a handsome bird and is a true pouter, and existed years before the whites were made. I want hours of relaxation to be harmless hours, and not, as they often are, harmful hours.

But there are not only artisans with more time to enjoy or waste, but there are men whose lives are very dreary at times. For instance, there is the bachelor curate in a big out-of-the-way straggling village, where his duties are spread over a large tract of country; where he has no neighbours, no society, no amusements but what he can make for himself; where he leads the life of a veritable hermit, and looks upon a face from the outside world as a perfect blessing. The poor man cannot always read, what is he to do? Why, if he had only a pet or two he would be much happier. Garden in his lodgings he cannot have; but if he could only have, say a pair of fancy pigeons, or even a pair of canaries, he would be the happier; or experimented upon breeding goldfinch or linnet mules. He would be sure in his parish to find some man or boy who was a fancier, and who would listen to a brother fancier in the pulpit with more respect than to one who only knew "parson talk."

Return we in thought to the new year. Let us welcome the new comer with a warm grasp. May he prove a happy one to all. A welcome, too, I send out in these lines to all. Welcome new correspondents who send us their observations; welcome old and tried correspondents. Welcome new readers, and may you enjoy and profit by our pages; nor let us forget our old readers, who have stood by us so many years. Welcome one, welcome all.—WILTSHIRE RECTOR.

SELECT VEGETABLES FOR SMALL GARDENS.

READERS of the Journal should now have little difficulty in ordering the best Roses, as the late election and all its bearings, every line of which I have read with profit, has made us all smiliar with the cream of the "queen of flowers" and the

emblem of "old England." Now I have been thinking lately, that if a flower which only blooms with most people for about two months out of the twelve, is under the necessity of being so prominently brought before the public, surely the space could not be considered ill applied that brought a few good vegetables under the notice of your readers. I have heard most enthusiastic admirers of flowers confess, that after all was said and done about their pets, the flower they esteemed most in the garden was the Cauliflower.

At the present time, when your advertising columns advise the publication of seed catalogues and many will be receiving their annual seed list, it may seem unnecessary to call attention to any particular class or variety of vegetable; but many would no doubt feel thankful enough to have some "practical hand" to look over and mark the best varieties from amongst the hosts in the catalogues. I have received my seed list to-day, and with the exception of a few new things I will mark the same this time as I have done on former occasions, and it is these I have selected in years past that I now wish to recommend to others; and I particularly wish it to be understood that every one of them has proved to be of a very superior description under no very "highly favourable" circumstances, but just with the attention given in an ordinary kitchen garden.

I will begin with what are always acceptable to everybody—Potatoes. For earlies I plant the following kidneys:—Myatt's Prolific, Early Sandringham, and Rivers' Royal Ashleaf. Second early—Huntingdon Kidney and Rector of Woodstock. Late—Red-skinned Flourball, the Old Regent, and Porter's Excelior. Of the newer American varieties I mean to devote a good breadth of ground this incoming season to Snowflake. I am fully convinced this is an excellent "poor man's" Potato, as it bears enormously, and the produce is of superior quality.

The most profitable crop of Cabbage I find to be that produced from seed sown in the autumn. Wheeler's Cocoa Nut and the old Early York are sown in August, planted out when ready, and cut for use in May and June. The stems are left in the ground, when they throw out many small sprouts, which are much thought of in the kitchen in autumn and winter. Drumhead stands the weather well, but it is coarse. Red Dutch is the only sort grown for pickling.

Early London is the variety of Cauliflower used for early produce, and after mid-summer it is succeeded by Veitch's Autumn Giant, which is still fit for use out of doors, and is undoubtedly the best Cauliflower extant. Snow's Superb Winter White and Waleheren are two excellent Broccolis. Dalmey and Strymer's Giant Brussels Sprouts when true are always worth their ground. The best Celeries are Major Clark's, Leicester Red, and Sandringham Dwarf White. Early Horn Carrot should always be sown for the first crop, and James's Intermediate Scarlet or Altriohann to come in late. Dell's Crimson Beet is not only the best for culinary purposes, but its foliage is more attractive than any other sort, and it does quite well to associate with flowering plants. The Student Parenip is the only sort I find it necessary to grow. When Myatt's Garnishing Parsley can be had true it is unsurpassed by any other I have seen. Onions are generally considered an important crop. The sorts of these I will name are James's Keeping and Nancham Park for summer sowing, Silver-ekinned for pickling, and Tripoli and Giant Rocca for autumn sowing.

Peas are always an important crop in all gardens. I will only name six sorts out of the many varieties now in cultivation. Early—Sangster's No. 1 and William L. General crop—Veitch's Perfection and Champion of England. Late—No Plus Ultra and Maclean's Premier. Dwarf Kidney Beans—Canadian Wonder and Osborn's New Foreign. The latter I find excellent for either forcing or growing in the open air. Broad Beans—Windsor Green and Beck's Dwarf Green Gem, and there are few which surpass the old Scarlet as a tall or running Bean for general usefulness, but Carter's Champion has larger pods. Small gardens should always be well provided with salads. The best way of doing this is to grow Lettuces of the All-the-year-round, Hardy White Dutch, and Victoria varieties in the Cabbage section, and Bath and Paris Green among the Coo or tall-growing sorts. Endive—Green Carled. Turnips—Early Snowball and Golden Ball. Spinach—Erickly. Rhubarb—Royal Albert and Myatt's Victoria. Leeks—Henry's Prize and Musselburgh. Radish—French Breakfast and Wood's Early Frame. Savoy—Drumhead and Tom Thumb. Vegetable Marrow—Custard and Moore's Vegetable Cream. Tomatoes—Hathaway's Excelior and New

Green Gage. Cucumber—for early spring, Telegraph; for summer, Telegraph; for winter, Telegraph.—A KITCHEN GARDENER.

THE NEW ROSE YEAR.

"The harvest now is ended, the summer days are gone," and yet every heart is joyous, every mouth uttering good wishes.

And why? At a time of the year when all nature is dead, when the sky is lowering, and the daylight so dim that the room in which I write is in semi-darkness; when snow or sleet is falling, and except in the conservatories of the rich no flowers are to be seen;—why should we be thus glad at heart? It is because at this season were brought gifts, the value of which is more than tongue can tell or voice express; flowers that never fade, but bloom on and on through all eternity. Yes, it needs not flowers to make our homes gay at this season; the evergreens do this, and also remind us of the life that never ends. And besides, now the darkest and gloomiest months of the winter season are over, the shortest day is past, and each day we live brings us nearer to the time when our Roses again will bloom, and our woods and lanes be carpeted with those wild flowers which Nature gives with so bounteous a hand to this favoured land of ours. When, therefore, I wish our readers a happy new year, I do so with all the heartiness with which this most hearty of all seasons inspires us.

This Journal has ever had a more personal and closer connection with its subscribers than most others can boast of. It has ever tried, and I think has succeeded in the attempt, to make it a friend and adviser to each one of its readers. Its columns will attest that there is no subject in horticulture, or indeed in any other department with which the Journal has to do, on which advice is not sought for, and the best assistance that is procurable is given with readiness and pleasure. But more particularly have I welcomed all contributions and questions upon the subject of the queen of flowers. I think that it has earned, as indeed it possesses, the name of "The Rose Journal," although that name is not emblazoned on your coat of arms (the writer of this most heartily wishes it was). There is scarcely a number issued which does not contain an article or letter upon that subject of subjects—the queen of flowers, and I consider it a very black Thursday indeed when the Rose is not mentioned in our Journal. To rosarians, then, and others also, I offer sincerest good wishes, and also congratulations. I consider that the last year saw a very great increase in the number of the cultivators of this lovely flower, and from the letters I receive I think I am entitled to form a good judgment on this point.

The horizon for Roses is very clouded, for some of the great companies who used to entertain the worshippers of Rosa have closed their doors, and for a time a deluge of incoherency seemed to be sweeping all Rose shows away; but the storm has lifted, and the dawn suddenly brightened. London will not be without its Rose show, and the Rose's liege and loyal subjects will not have to be contented with paying their addresses in provincial courts.

Undoubtedly the event of the Rose year has been the formation of the National Rose Society. I never remember to have attended a meeting where more unanimity of feeling and enthusiasm was evoked than at the Rose conference held on that gloomy day in December at the Horticultural Club; and the mention of this Club reminds us that another step has been taken in advancing horticulture, which it would be difficult to overvalue. It will be evident to all how useful and convenient it must be for horticulturists from all parts of England to have a place in the metropolis where they can meet and discuss horticultural matters or arrange shows; and a most telling proof of its value was afforded by the very meeting of which I am speaking. If the Club had not opened its doors to us on that occasion we should have had to engage a room, and at the very outset a difficulty would have been felt in the worst of all troubles—who is to pay? But now we always shall have a Club where we can meet, converse, and enjoy ourselves, as well as hold committee and annual meetings. I wish, therefore, every success to the Horticultural Club.

Once more, then, let me wish you all a very happy new year. I thank your contributors, and hope they will continue to instruct and entertain us. Nor do I forget your staff, and all the rest who have helped to make this Journal what it now is; and I hope that it may long continue to bear the name of,

and prove worthy of the honour of being, the "Rose Journal of England."—WYLD SAVAGE.

NOTES ON PINE APPLE CULTURE.

THE Pine Apple is found growing wild in Brazil and in different parts of the West Indies, from whence many inferior fruits are still imported. It was introduced into this country in the eighteenth century. For many years afterwards its cultivation was very imperfectly understood; but this has not been the case for some time, as many intelligent gardeners have for years paid great attention to its requirements, and in many places it is well managed. It has never been grown in this country for market so extensively as Grapes or some other fruits, but it was grown remuneratively for this purpose by some until its cultivation was begun on a large scale a year or two ago in St. Michael's. The low prices at which the showy fruit from there can be sold in our markets has caused some market growers to cease its cultivation; and some would have us believe that the St. Michael's fruit will be the means of stopping the cultivation of Pine Apples in many private gardens. But that is not my opinion, nor do I think it can be the opinion of any person who reads the *Journal of Horticulture*, as there is hardly a week passes without one or more Pine Apple questions being replied to through your answers to correspondents, and this, I think, is a very good proof that the queen of fruits is still in as great demand as ever. Besides, consumers of market fruit are, as a rule, those who have no means of growing it themselves, for those who are in a position to grow it must prefer that of home production to the very best of that imported. However, I have no intention of writing an argument in favour of the continuance of Pine Apple-growing; that would be quite unnecessary.

Propagation is accomplished from suckers, which are produced from the main stem of the plant. It is the best plan to have some regular time to take off the principal batch of suckers; but at the same time suckers may be taken off and rooted successfully at any season. They do not root so quickly or freely in the winter time, however, as in the long days, and those inserted in winter must have the assistance of a steady bottom heat of 90°, with a top heat of 60° and a moist atmosphere. In taking the suckers from the old plants at any time they must always be carefully severed close to where they adhere, so as to keep all the little roots entire which are clinging round the base of the sucker. A few of the lowermost leaves must be pulled off with the hand, and then the suckers are ready for potting. I may remark here that very large suckers are not the most desirable, as they seldom make the best plants in the end. Suckers from 12 to 18 inches in length are the best. When they have to be planted prepare as many clean 6-inch pots as there are suckers; put about 1 inch of broken crocks in the bottom of each with a little moss over the top, and then put a sucker into each pot, using good fibrous loam mixed with a little boneseal or fine bits of charcoal. The plunging material may consist of either tan or leaves, some prefer the former, others the latter. Both are about alike good, but the tan is much the easiest worked amongst. Its depth for all kinds of plants should be from 18 to 30 inches. The suckers may be plunged 15 inches apart each way. The soil should be moderately moist at potting time, and no water should be given until the young roots are at the edge of the ball. In warm weather, or when the air is rendered dry from strong fire heat, the suckers must be moistened overhead occasionally. As soon as the roots have made their way into the soil give it a good watering. September is the best time to take off the main lot of suckers, when they soon root and do well throughout the winter.

After they are rooted and watered once they frequently do not need any more water for six or seven weeks. When the soil of those rooted in September is matted with roots the plants should be turned out of their pots, reducing the balls, disentangling the roots and repotting into the same sized pots. Replunge the pots, and as soon as the young roots begin to spread in the new soil the plants must be shifted into their fruiting pots. Those put in as suckers from now until February or March will need no other potting before going into the fruiting pots. The fruiting pots should be 10 and not exceeding 12 inches in diameter; as good fruit may be grown in these sizes as a 16-inch pot. More drainage is needed in the fruiting pots, and the soil must be rougher at this than the former potting.

In potting let the top of the small ball be an inch or so below

the surface of the fresh soil, and it should be left at least 1 inch below the rim. The soil, too, must be made very firm with a blunt-ended piece of wood, and after potting the pots should be firmly plunged in a freshly made up bed, where the bottom heat will soon rise to 85° or 90°. The plants must be treated like rootless suckers until they begin rooting into the fresh soil. In the summer they will need water about once a week. This with air-giving and keeping the atmosphere moist are their principal requirements throughout their growing period.

The Queen variety needs different treatment from any of the others when the plants are of a fruiting size. All the other kinds may be kept growing on slowly until they fruit, but the Queen has to be rested and partially starved before it can be made to show fruit. Plants put in their fruiting pots in April should be grown sharply on until the end of September, when water and heat must be gradually withheld from them until the plants have ceased growing, which they will do in a heat of 50°. They should remain like this until about the first week in January, when a fresh bed must be made ready for them, and in this they must be plunged and started as they were when shifted first into their fruiting pots, but with this difference, that they must be watered thoroughly immediately they are replunged, and the soil and atmosphere must be kept moist, and the temperatures should be, bottom 85°, top 70° and 75°, until the fruit appears and for some time afterwards. This treatment seldom fails to bring up the fruit, and if the plants have been well grown and matured in autumn there is not much danger of failure. Still, even with the best of growers the Queen is often found to be uncertain, and those with little experience would do well to increase other surer sorts. Smooth-leaved Cayenne, Black Jamaica, and Charlotte Rothschild will all show fruit without being starved or started with a bounce.

All plants with green fruit should be constantly kept in a moist condition at the roots. As soon as the fruit begins turning yellow give the plants no more water until the fruit is out, then water liberally to bring on the suckers. When mature water is used a little guano is the best.

I have said little about syringing and temperature, nor are any lengthened instructions necessary. The temperature should always be regulated by the condition of the outside atmosphere. It is always better for the temperature to rise and fall with this, than fire hard to keep up a given heat in extreme cold weather. I have seen Pines kept at nearer 50° than 65° throughout the winter with the very best results.

Queens produce suckers more freely than any other sort. When the fruit is cut the suckers may be taken off and potted, or the plants with the suckers attached may be laid in a spare corner until a lot of them can be put in together. In the dull winter days all Pine plants, especially those in fruit, should be exposed to all the light possible, and no drops of water from the roof must be allowed to fall into the centre of any of the plants or they will decay.

It often happens, especially with Queens, that a number of them will ripen their fruit at one time. This is not desirable, as a succession of fruit for a long period is what is wanted. Laying a piece of newspaper over a few of them so as to partially exclude the light for a week or two before they begin colouring will make them longer in ripening than those not so treated; and when they are ripe, by removing the plant and fruit into a cool room will preserve them in good condition for six weeks or two months, so that with a little of this kind of scheming a long succession of fruit may be had from a number of plants that showed fruit together.

In some large places there is house after house devoted to Pine culture; but although this is necessary to keep a large supply of fruit, small demands may be met from a limited space. A good many fruits may be cut annually from one small fruiting house, a pit for successional plants, and a frame for suckers. Some growers approve of planting them out in beds; I would not advise small growers to adopt this plan. Good fruit may be had from it, but there is much inconvenience attached to it. Supposing a bed to be full of large plants now, some of them may show fruit at once, while others may not do so for six months after this, and the bed cannot be cleared or replanted until the last of the plants have been removed; whereas when in pots the late-fruiting plants can be gathered together from amongst the early plants, plunged together, and the vacant space filled up with others.

Insects are not very partial to Pines. Mealy bug and scale are their greatest enemies, and they are generally introduced by other plants. When the Pines do become infested to any

great extent the best way is to clear them out, clean the house thoroughly, and begin with a fresh stock.—M.

JUSSIEA GRANDIFLORA.

We are indebted to Carolina for the plant our figure represents. It is said to have been introduced in 1812, but appears to have found little favour among cultivators. Loudon pays a poor compliment to this family of plants, regarding them as unworthy of the name of Jussieu. *Jussiea grandiflora* is an aquatic plant. A greenhouse is suitable for its cultivation. Though possessing no great beauty it might be included in the collections of those desirous of growing plants of this nature. It may be increased by seed sown as soon as ripe, in pots drained and filled with a compost of loam and sandy peat and placed in

Fig. 1.—*Jussiea grandiflora*.

water; also by division. Where there is no aquarium large basins or bowls may be substituted. I have sometimes beaten clay firmly in the bottom of ordinary garden pots for some of my aquatic pets, and they have succeeded beyond my expectation. It is to be regretted that there is not more interest taken in the various species of water-loving plants, which when once established require but little attention.—N.

LATE-KEEPING GRAPES.

EARLY decaying in many instances would be more correctly descriptive than late keeping as applied to bunches which were intended to hang until March, but decayed before January.

A variety of causes may have contributed to the decaying of Grapes, such as too much moisture in the air, too much foliage on the Vines, too many plants in the vinerias, too late or insufficient ripening of the fruit, and insufficient thinning-out of the berries. These are contributory causes of early decay, and they have all of them been aggravated or intensified by a peculiar incidence of the autumn and winter which has not been sufficiently understood.

There have been periods during the present autumn when good housewives have been sorely puzzled at the unwonted dampness of their dwellings—the “walls have run down with water,” the floors and ceilings have been damp, and even the “bedding has felt clammy.” Such household complaints must have been very familiar to many gardeners, some of whom have not been able to account for the cause of the “walls sweating,” while others—who are “given to thinking”—have understood the matter perfectly. But what has this to do with Grapes? Much, for Grapes will “sweat,” as it is erroneously

termed, under the same conditions as will walls. But in truth it is not “sweating” at all. The moisture which has puzzled good women did not come out of the walls, nor did that perplexing some men come out of the Grapes.

The season has been unusually mild and damp, yet occasionally a few very cold days have been experienced. These cold days have been followed suddenly by unusual mildness, and it has been on the sudden rising of the temperature after the cold days when the “sweating” has occurred. If the surfaces of walls, glass, calico, or Grapes become unusually cold and the temperature surrounding them suddenly rises, the cold surfaces become condensers, and the moisture of the air is transformed by them from the invisible to the visible state. The greater the difference in the temperature of the surfaces and that of the surrounding air, the greater is the quantity of moisture that is precipitated. The moisture does not come out of the walls and the Grapes, but out of the atmosphere.

That is an important fact to be remembered; and another equally important is, that the moisture is governed by the temperature. It is not enough that the air of a vinery where Grapes are required to be kept dry should be provided with a steady or a minimum temperature of 40° or 45°, for if a house has been at 45° for a week, and the outside temperature suddenly rises to 55° (which has more than once been the case lately), moisture will inevitably be condensed by the cooler surfaces of the Grapes. When the air outside is clear, cool, and dry, as it frequently is in winter, then there is little or no moisture to precipitate on the Grapes, and a house temperature of 40° is safe; but when the prevailing outside temperature is high, also moist, then the inside temperature must be high too, or the Grapes cannot be kept dry.

The condensation of moisture is doubtless understood by many gardeners; a few there are, however, who do not fully appreciate it, and for the sake of these few the matter may well be made plain. Take a cold slate—a common school slate—and cover it with writing on a wintry day; step with it into a heated plant stove, and in less than five minutes the writing will be invisible, the slate having become covered with dew condensed from the warmer atmosphere. Now place the slate on the hot-water pipes and heat its surface, and the writing is again visible, and continues so as long as the slate is kept in the house. That is just what walls and Grapes do after a week of cold weather being followed by a sudden rise of temperature. Their surfaces do not become warmed so quickly as does the air surrounding them, and hence the “sweating”—the condensed moisture—causing in one case decay, and in the other discomfort.

By taking cognisance of the principle of dew-formation, and guiding the temperature accordingly, much may be done in preserving Grapes in a season like the present, but without this knowledge, or without having acted in accordance with it, many Grapes have decayed prematurely. Yet after doing all that was possible the fact still remains that the season has been unfavourable for the sound-keeping of Grapes, and it is only fair that all concerned should “know the reason why.”—A NORTHERN GARDENER.

THE PERSIMMON.

In your Journal of November 30th in an article on *Diospyros Kaki* you repeat the popular opinion that the *Diospyros virginiana's* fruit “is not palatable until frozen.” Allow me to say that this is a fallacy. The Persimmon, as it is known through the southern half of the United States, is quite variable in the size, season, and quality of its fruit, and I have no doubt will be ultimately developed by selection into a valuable species of fruit. I have seen ripe specimens in this latitude (89° N., about St. Louis) as early as the end of August, whilst the fruit of some trees hardly ripens at all, or if so, imperfectly, by the time cold weather begins. But the ripening and sweetness seem to depend entirely on the length and heat of the summer, and not at all on the subduing powers of early frosts. Hot summers produce early-ripened delicious fruit, cold seasons and high latitudes produce poor fruit. Arthur Bryant (a brother of the poet Bryant), living at Princeton, Illinois, about latitude 41½° N., tells me that in some seasons the Persimmon with him does not ripen, and he thinks the frost has nothing to do with its maturing. He has trees nearly forty years old of his own planting, and has observed them closely.

The Persimmon varies also a good deal in size. I have heard of specimens 2 inches in diameter, and have seen them

as small as three-quarters of an inch. They vary in quality. Some are delicate, others always dry and tasteless or astringent. The reason of ripening by selection of varieties could undoubtedly be made to cover two months or more. It seems to be a fruit of great capabilities; and but for the fact that we had so many Apples, Pears, &c., provided ready to our hand by the mother country, this, as well as other native fruits, would now be well on in the course of amelioration.

This was a favourite fruit of the aborigines, who dried it for winter use, and it is mentioned by all the early travellers—John Smith, Marquette, Charlevoix, &c., under various hard-spelled names, such as *Plaquevine*, *Patchumen*, &c. It is still said to be a great favourite with the Indians of the south-west.

I am inclined to think that the astringency complained of in the *D. Kaki* by your correspondent, and which is a marked characteristic of the unripe *D. virginiana*, will be found to be the result of insufficient light and heat in your English climate. Judging from analogy a high and long-continued temperature under bright skies will give the best fruit.

I have omitted to add that there are several cases on record of seedless varieties of the Persimmon. In one case an attempt made to perpetuate this peculiarity by grafting failed from the curious fact that the seedless variety when grafted on a non-bearer began to produce fruit with seeds. (See *Gardeners' Monthly* for 1876).—W. C. FLAGG, *Moro, Ill., U.S.A.*

ROSES IN SMALL GARDENS.

I AM glad to see that "E. M., *Croydon*," has modified his sweeping condemnation of poor Rose-growers, and I think if he would take the trouble to go to a village flower show the Roses he would see there would make him more lenient still. But as he seems a Rose enthusiast I would suggest that he publish a pamphlet at a cost of 1*d.* or 2*d.*, with rules for general Rose-growing, which I feel sure would be gladly welcomed by vicars of rural parishes anxious to encourage the cultivation of flowers among their parishioners.

I think "E. M.'s" condemnation too sweeping when he says every other garden throughout Rose-growing England can only produce "miserable starvelings." I have been surprised in my country wanderings at the beauty of the Roses generally grown, especially by cottagers. Granted "the names of the varieties" would prove them to be old-fashioned, but these are still admired by some people, as I was glad to read in the pages of this *Journal* a few weeks ago. Before finally quitting this subject I must just add, that I write entirely on behalf of cottagers and others with small plots of ground who are Rose-lovers, for I do not cultivate one.—R. S.

ALLAMANDAS.

AMONGST the many stove plants cultivated for exhibition purposes or otherwise none are more frequently met with than *Allamanda*, and, apart from exhibition purposes, none are made less use of. The flowers are considered by most gardeners as worthless for decorative purposes because they will not last long. It is true they will not last if cut with a long portion of wood attached to them and arranged loosely in trumpet-shaped vases, for in this way the leaves soon become like so much wet rag. A system that I have practised for some time past is to fill a glass vase, similar to a dessert dish (with or without a pedestal), with Swiss moss, and elevate the centre above the sides of the dish and fill it with water; then gather a quantity of single blooms, and arrange them so that the broad segments of the flowers will rest on the moss. Certainly they have a flat appearance, but the introduction of foliage or a few Fern fronds wonderfully relieve the arrangement, and a vase filled in this way is not to be despised, particularly at this dull season of the year, when good flowers are scarce.

Allamandas are not at all difficult to please with soil. I have a number of plants growing most luxuriantly in road scrapings and horse droppings. They have rambled over all the roof of the aquatic house, and frequently require thinning to admit light to the *Nymphæa* in the tank below. The plants commenced flowering in March, and have continued producing thousands of flowers until the last fortnight. When the wet weather set in the plants began to relax. I feed liberally with liquid manure, and allow the long shoots to ramble about and hang loosely from the roof. In this way they present a natural and wild appearance, and look much better

than if tied closely to rods and rafters, as nothing mars the effect of a plant more than by tying and twisting it the reverse of nature. The variety I grow principally is *A. Hendersonii* or *Wardleana grandiflora*. It is of a beautiful straw-yellow colour, and well deserves more extensive cultivation.—JAMES OLLERHEAD.

A PRACTICAL GARDENER'S IDEA OF A NATIONAL HORTICULTURAL SOCIETY.

A CRISIS appears to have overtaken the Royal Horticultural Society. It is proposed by an influx of fresh blood to resuscitate the Society. Guinea fellowships are proposed as (I suppose) the nucleus around which horticulturists will rally. Whatever may be the upshot with the Royal Commissioners, it may be that the Society will make a retreat to Chiswick, coming to arrangement with the Commissioners for the fortnightly meetings at South Kensington and periodical exhibitions. This would undoubtedly help the Society in its present dilemma, but the privileges likely to accrue to the guinea fellowship—viz., admittance to all the Society's shows in London and the provinces, and to all minor exhibitions of fruit and flowers held at the fortnightly committee meetings, and daily admittance to the Chiswick Gardens, are privileges of no very great importance to provincial Fellows, who would be very little benefited by its shows and gardens, though of great value to those within easy distance. Distance alone would influence many to withhold their support from a central society having no advantages to offer except shows they can at most but occasionally visit, the garden for the same reason being practically sealed. "Old associations" would not avail to retain any great number of patron Fellows, who principally are most interested in the gardens at South Kensington. Their luxury gone, what could they be expected to do but to become guinea Fellows or turn their backs upon the Society? Some would no doubt take to great an interest in horticulture as to continue their subscriptions as patron Fellows, and would not experience any disappointment in having few or no privileges. It is, however, proposed that patron Fellows subscribing four guineas receive a ticket admitting self and friend, and the right to a second ticket admitting their head gardener to all the Society's shows.

Now, it appears that privileges are after all to be measured by the amount of guineas subscribed. Four-guinea subscribers are to have practically three tickets, and guinea subscribers a ticket to all the Society's shows, exposing the broad basis upon which a society of this kind ought, if it is to prosper, to be founded. There ought not in any national horticultural society to be any fancy privileges, but an equality of subscription conferring equal advantages. It ought to be instituted upon principles of reciprocity, subscribers encouraging by their subscription the advancement of horticulture, and receiving in return the gratification that the Society is doing useful work—truly horticultural work—by investigation and propagation.

The class most directly interested are those contributing with a view to benefit direct or indirect, and those who include its workers, who will by investigation and information do the society much valuable service, far exceeding any money subscription. I need not do more than mention the advantages accruing to possessors of gardens, gardeners, and nurserymen. Employers would have the advantage of the society's work, be served by a higher stamp of gardeners, and those would, from their increased proficiency, attain to a better social position. Commercial members prospering from demand for the plants required for embellishment and for useful purposes.

I have an idea of a Royal horticultural society. The present one rid of the South Kensington Gardens would, with its charter and the Chiswick Gardens, be the soundest foundation upon which to build a school or college of horticulture as free in principle and constitution as are most of similar institutions upheld by subscription. Before proceeding with an outline of a national society, it may be as well to begin with the Royal Horticultural Society's disaster—namely, its league with the Royal Commissioners. The only way to satisfy the debenture-holders would probably be for the Commissioners to take upon themselves the responsibility of the whole or part of the debenture-holders' claim, and convert the gardens into a recreation ground or fashionable garden, maintained by the leaseholders in the neighbourhood, or converting it into a company. The Commissioners to compensate the Society for its outlay upon the gardens by a grant of so much of the building and gardens as would be required for the Society's require-

ments for offices, meetings, and exhibitions, or, failing that, granting a monetary consideration. But as there is such unanimity shown in respect to the suitability of the present site or locality for the Society's meetings and shows, why not seek government aid in respect of the present buildings and ground requisite for the successful carrying-out of the Society's objects? Surely the time has arrived when horticulture should take its rank as one of the institutions of a great people.

The Chiswick establishment should be continued as an experimental garden and school of horticulture. Students qualifying for gardeners to be admitted upon the recommendation of Fellows, and these students to form the labour staff of the garden at stipends suitable to their respectable maintenance, or such remuneration as the labour performed deserves. Other students to pay a fixed rate per annum as may be determined on from time to time by the executive, and if boarded pay for their maintenance; they not to perform any menial work, or only at the instigation of the professor, as may be necessary for instruction such labour may be performed. This latter class of students it is presumed will be sufficient to meet the salary of the Society's professor of horticulture, the students to have free admission to all lectures given in any of the Society's places of meeting, whether the lecturer gives his services gratuitously or otherwise. The Society to hold four exhibitions in each year in London or its environs, and prizes offered at each for plants, flowers, fruit, and vegetables, and once every year a national exhibition in the provinces, commencing with London the first year. Its first provincial show might be held in the north, its second in the east, third in Scotland, fourth west of England, fifth Ireland, sixth that locality or place in England holding out the greatest inducement to the Society for the holding of its exhibition, the seventh to be an international one held in London, the second international held in Scotland, and the third in Ireland, every seventh exhibition held by the Society to be international.

Assistance should be given to provincial horticultural societies in the framing of their schedules and rules, placing at the command of societies in union with the Society a censor or judge to act with those appointed by the Society, and between whom the Society's official shall act as umpire. No fee to be given by the local society to the judge or charged by the Royal Horticultural Society; but the society making use of the Society's officer to pay his travelling expenses, with such allowances for hotel expenses as shall be determined by the Royal Horticultural Society. It shall be the duty of the judge to award, with the approval of four Fellows of the Royal Horticultural Society, the silver and bronze medals to such productions as in his and the Fellows' judgment are most deserving of special recognition through evidence of superior cultivation. N.B.—If there be a difference of opinion in regard of the awarding of the medals, there shall be no award in that case unless two of the Fellows agree with the Society's censor. In the absence of Fellows of the Society the censor shall have the aid of four horticulturists approved of by the local society's secretary, and with their assistance award the medals of the Royal Horticultural Society, having at least two approvers in each case of his award.

The Royal Horticultural Society should encourage in connection with provincial horticultural societies the establishment of gardeners' institutes by correspondence, and a copy of its journal in exchange for papers read at the institute.

Correspondence to be opened and maintained by the Royal Horticultural Society with colonial and foreign horticultural societies, and an exchange of publications.

A library to be formed as complete a kind in respect of horticulture and allied sciences as possible, which shall be free to all members of the Society.

The Society to publish a journal monthly containing a full report of the work performed by the Society, and if this be of a kind exceeding 1s. in cost monthly, papers shall form a separate publication, and sold in book form, but from publication in the gardening periodicals would be of little value; and at the end of each year a complete account be published of the state of the Society's finances and affairs.

Reporters to have free access to all the meetings of the Society with a view to greater publicity than would be afforded by the journal.

I shall say very little of the Society's constitution. It needs not revolution but reform. The present Council is perhaps as good as any of its predecessors. Whatever the Council be it must be prepared to do the bidding of the subscribers. No

constitution would answer so well as a crowned republic. A President—His Royal Highness the Prince of Wales, with power to approve a deputy appointed by the Council. A Council of Vice-presidents to consist of thirteen members elected by the Executive Council from those deserving of distinction from advancing horticulture, but none but noble or wealthy individuals (patronising horticulture enthusiastically) to be eligible. An Elective Council of thirteen elected by the votes of the members for seven years, vacancies to be filled by the Elective Council nominating the most likely person or persons for the vacancy or vacancies, whose election shall be consequent upon the votes of the subscribers, provided the nomination does not receive the approval of the Council of Vice-presidents and President. When those approve the nominations of the Elective Council, that body shall by vote fill up vacancies in its ranks. The Vice-presidents' Council to make suggestions to the Elective Council upon subjects it may see fit, which the latter shall consider and take such action upon them as in their opinion would be for the interests of the Society. The Elective Council shall transact all the Society's business, having full control of departments; and all its meetings public—open to reporters.

Fellows subscribing £5 5s. to have two ivory tickets, each ticket admitting two persons to all the Society's meetings, shows, gardens in London or elsewhere, promoted by the Society, with copy of journal, and the right of nominating one candidate to the school of horticulture, and five votes upon an election. Fellows subscribing £4 4s. to have one ivory ticket, admitting two to all the meetings, shows, and garden of the Society, two tickets admitting to all shows and garden, with copy of journal, right of nominating a candidate for admission to school of horticulture, and four votes. Fellows subscribing £3 3s. to have three tickets (one ivory admitting two) for all shows, garden, and meetings, with copy of journal and three votes. Fellows of £2 2s. to receive an ivory ticket admitting two, and one ticket of admission to all the meetings, shows, and garden, with copy of journal and two votes. Fellows subscribing £1 1s. to have ticket for all meetings, shows, garden, with copy of journal and one vote.

No Fellow to have any right to cuttings, seeds, or plants, nor any produce or result of the Society's garden or labour, but the whole produce of the Society's garden to be disposed of to the best advantage for the general benefit of the Society.

Provincial horticultural societies contributing £10 10s. per annum to receive the services of a judge appointed by the Royal Horticultural Society, and three silver and three bronze medals, with copy of journal, and ten votes. The subscription being given in the name of the committee of the society wishing for union with the Royal Horticultural Society by their secretary. Societies subscribing £5 5s. per annum to have the services of the Society's judge, two silver and two bronze medals, with copy of journal, and five votes. Societies subscribing £4 4s. to have services of judge, one silver and two bronze medals, with copy of journal, and four votes. Societies contributing £3 3s. per annum to have services of judge, one silver and one bronze medal, with copy of journal, and three votes. Societies contributing £2 2s. per annum to have one silver and one bronze medal, with copy of journal, and two votes. Societies subscribing £1 1s. per annum to have one silver and one bronze medal, and one vote. The medals in the two last instances to be awarded by a judge appointed by the committee of the respective society, and approved in his award by at least one Fellow of the Society.

Gardeners' institutes or improvement societies contributing £2 2s. per annum to have presented one silver medal, which shall be awarded by the votes of its members, choosing three persons to adjudicate upon the papers read before the members of the institute, who shall award the medal to the writer of the paper which in their opinion appears most deserving, but the Royal Horticultural Society shall have the right of rescinding any award which shall be found undeserving, advising the institute to select other two for distinction, and upon the three being submitted to the Royal Horticultural Society the latter shall name the most desirable, and the medal shall be awarded accordingly. The institute to receive copy of journal and have two votes. Institutes contributing £1 1s. to have copy of journal and a bronze medal for awarding to the writer of some approved paper read before the Society, and one vote.

All voting to be by voting papers, stating the cause and object of the election, and forwarded to every Fellow, society, or institute entitled to vote, which filled up are to be returned to the Secretary. The voter not to sign his or her name, but

distinguish by marks X prefixed to the name of the candidate or object voted for the desire of the voter in marks he may be entitled to. Number upon the voting paper will be sufficient to prove the voter's right to vote, checks being kept by the Society.

All students passing the examination of the School of Horticulture to be admitted Fellows free for three years, conferring the privileges of a guinea-subscribing Fellow, but without right to vote, except by contributing £1 ls. per annum.

I have only to say a few words in respect of gardeners. They ought to contribute of their own accord and not have any inducements held out to them by their employers being Fellows.—G. ABBEY.

VEITCH'S AUTUMN BROCCOLI.

This variety of Broccoli sent out by the Messrs. Veitch seems to me to be quite distinct from any other I know, and, like the Autumn Giant Cauliflower, is a grand acquisition to our list of autumn and early winter vegetables.

Having been once or twice "smiten" with the glowing descriptions of some newly-introduced vegetable, but found after trial to have been "bitten" by them, I did not last spring order this Broccoli; but my friend Mr. Louden, The Quinta Gardens, kindly sent me a number of plants for trial, and these have turned out all that has been said of this Broccoli. The stem is short and stout, the heads well "protected," close, and compact, and of excellent size for table use. I cut the first early in November, and am still cutting as wanted now (December 22nd.) We had 10° frost in November, and while numbers of Autumn Giant Cauliflowers were destroyed, this Broccoli was uninjured.

By making an early and late sowing of this Broccoli the cutting season might be much prolonged. To those who have not grown it the past season I would say, Do so next, and you will not be disappointed. I may add that Snow's Winter Broccoli is now (last week of December) coming in, and although useful, cannot for a moment compare with Veitch's, the heads of Snow's being rather open and yellowish in colour.—JAMES ADAMSON, Brynkinnall.

NOTES AND GLEANINGS.

We are informed that at a meeting recently held at Carlisle it was decided to offer £1000 in prizes at the INTERNATIONAL Show to be held in September. We are glad to learn that the Committee have met with much encouragement and many supporters, and they confidently expect that the Carlisle Show will be a great success.

"J. N." states in reference to the HARDINESS OF LYCOPodium DENTICULATUM recently alluded to by Mr. Luckhurst, that it does not succeed well in his garden in Cambridgeshire, and asks if Mr. Luckhurst will state how many degrees of frost the plants he refers have endured without injury.

At a recent meeting of the SCOTTISH SEED AND NURSERY TRADE ASSOCIATION an important discussion was conducted as to the best means for securing the sale of unadulterated seeds. Mr. D. Cross, Glasgow, was elected President of the Association for the ensuing year; Mr. Muir Crawford, Leith, Vice-president; and Messrs. Syme, Mackintosh, J. Walsh, Laird, Edinburgh; Hunter and Sadler, Glasgow; Ballantyne, Dalkeith; Alex. Cross and Hope, Leith; and Palmer, Annan, were appointed the Acting Committee. On the motion of Mr. Sadler, Glasgow, it was remitted to the Acting Committee to consider the propriety of drawing up, in conjunction with the law agent of the Association, a non-guarantee clause for seed to be adopted by the members of the Society.

It is seldom that APPLES are afforded the assistance of SOUTH WALLS to ripen them, yet some of them cannot be had in perfection in the open garden, notably the Calville Blanche. The plan of growing this distinct and desirable Apple as adopted by Mr. Haycock at Barham Court, Maidstone, is highly worthy of notice. Good crops of it were growing on horizontal cordons trained by the sides of the walks, but the best were on a wire trained about a foot from the ground and the same distance from the south wall of the garden. Those trained the heat reflected by the south wall was utilised by the fruit without the trees encroaching on the wall's surface. Neither does a strand of wire stretched in such a position interfere with the crops of the border, but it does enable Apples of splendid quality being produced when they cannot be had

of similar excellence by the usual mode of growing them in exposed places. The plan is of course equally adaptable to Pears, and it appears worthy of being more extensively adopted. If it answers, as it undoubtedly does answer, so well in the south, it may be supposed to be of still greater value in colder localities.

THE COLD WEATHER in London which suddenly set in immediately before Christmas, changed as suddenly after the "festive day." The temperature has been unusually high for several days, higher indeed than the average for the same period for a great number of years past. Autumn-sown crops, both of vegetables and flowers, are very forward, and fruit buds are swelling freely. Cauliflower plants in frames and under hand-lights are much larger than they should be, and it is feared that many of the plants will "button." Those who have plants in this state will do well to sow seed at once under glass, and thus make timely provision, preventing as much as possible the prospective blank in the supply of an important crop—early Cauliflowers.

MR. MOORMAN writes to us as follows in reference to the SCARCITY OF HOLLY BERRIES:—"We have six large trees, which are noted for their bearing propensities. During the eight winters I have had them in my charge I have never known them without a crop before this year. One of my workmen says we ought to have dug around the trees and watered them, for quantities of berries were swept up during the past summer. Doubtless the drought had something to do with the failure, but I also think the severe frosts occurring during their blossoming period was the principal cause of the scarcity. The trees in question, which cast their berries in a green state, were growing under some large Oaks and may have been sheltered.

A CORRESPONDENT writes to us as follows:—"I think in these days of elections of fruits and flowers that an ELECTION OF GRAPES would be both interesting and useful, and would prove a guide to many amateurs and others who contemplate planting, but who are bewildered amongst such a number of varieties and likewise conflicting opinions. Perhaps some of your readers will kindly enlarge on this subject."

MR. CHRISTIE, The Gardens, Orton Hall, Peterborough, communicates his success in CUCUMBER-GROWING. Last year he cut nearly two thousand Cucumbers from one span-roofed house 30 feet long by 11 feet wide. The sort he grew was Dixon's Imperial Frame; fruit about 15 inches long, of superior flavour. He grew Telegraph in the same house from seed sown ten days before the Imperial Frame, yet the latter was much the earliest in use, and he recommends it both for summer and winter culture.

ROSES UNDER UNFAVOURABLE CIRCUMSTANCES.

MUCH valuable information has been elicited through your Journal for the benefit of those Rose-growers who are favoured with fairly good soil and situation; but others also wish to know how much can be done by skill and proper selection for such unfortunate as are on a barren sand and in a smoky cold situation.

I have with scant success tried numbers of Roses recommended for smoky situations, but my experience does not accord with the lists sent out by nurserymen for such situations. The only Roses which will thrive and bloom satisfactorily through plentiful manuring are Gloire de Dijon, Prince Camille de Rohan, Baronne de Rothschild, Comtesse of Oxford, Général Jacqueminot, Fisher Holmes, John Hopper, Madame de Cambacres, Victor Verdier, Anna Alexieff, and Duke of Edinburgh, all on the Manetti, and Souvenir de la Malmaison on its own roots.

My object in writing is to give and to draw forth experience from those in like localities and placed on dry barren sand. Doubtless many other Roses besides those named may grow equally well, and hoping to elicit information I sign myself—SAND HILLS.

MRS. PINCE'S BLACK MUSCAT GRAPE.

I HAVE grown the above-named Grape for a great number of years, both in an intermediate or mixed house and in a late house, and, except on one occasion, the Grapes in the earlier coloured better than those in the late house. We have generally had fruit hanging in the late house until April, and the

Vines naturally start growing at that time; but this season has proved too short for the ripening of some sorts of Grapes which were started at the time named. Alicante and Lady Downe's have finished fairly, but Mrs. Pince is badly coloured, and even White Tokay is not what it should be for hanging late. We have resolved to start our late house a month earlier this year, and do not think that Lady Downe's or Alicante will suffer by the change.

With regard to there being two varieties of Mrs. Pince, I scarcely think there is sufficient grounds for supposing that to be the case. I believe I suggested some two or three years ago in these pages the possibility of there being two varieties, my remarks being based on the apparent difference between Vines growing in an intermediate house and others in a late house. Since then the Vine in the late house has become much more vigorous, the berries swelling more regularly, and in every respect except colour are quite equal to those on the Vines in the other house.

I have found Mrs. Pince a Grape that is much slower in starting, and keeps lagging behind in all stages of its growth when grown with other sorts, but more especially at the ripening period. I think if it was grown in a house by itself, and received suitable treatment, it would reward the cultivator. Would any who have had the opportunity of growing it alone give us the benefit of their experience?—R. INGLIS.

LIMATODES ROSEA.

WITH no special accommodation for Orchids I do not at present grow this plant, but I mentioned it as a very desirable Orchid, unapproached in my opinion in loveliness by any other of its season, except perhaps by Calanthe Veitchii, the result of a cross by Mr. Downy between Calanthe vestita and Limatodes rosea. Yet I have previously had experience with the plant and never found it difficult to cultivate, hence my surprise at reading that so able a cultivator as Mr. Douglas could "make nothing of it."

It was treated the same as Calanthe vestita was—namely, potted in March or when the last signs of growth appeared, for on no account must it be allowed to root into the old effete soil. All the old soil and roots were removed. The pots were well drained, and the compost used was composed of equal parts of very fibrous loam and sandy peat, with the smaller particles or dust rejected, a third part in equal proportion of old cakey or dry cowdung and leaf soil, with a half part or piece of charcoal or potsherds, the whole well mixed together, potting rather firmly and rather high.

The plants were then placed at the back of a Pine stove, a succession house, having Vines upon the rafters at every 5 feet. The plants of Limatodes would be not more than 3 feet from the glass, and as the Vines were introduced in early March a slight shade was afforded. Water was given rather sparingly until roots were emitted freely into the fresh soil, and after that took place and the growth was free the supplies were very liberal, and after the leaves were full-sized liquid manure was given twice a week—diluted drainings of a dunghill—of the same strength as applied to some Fig trees. The Limatodes were sprinkled overhead twice a-day, and the house was damped at noon.

In September the plants were placed on the back fine of another Pine pit and fully exposed to light. They were kept well supplied with water and liquid manure until the flower escapes appeared from the bases of the pseudo-bulbs, when the watering was gradually reduced; but they were still kept moist, not being allowed to go dry until they had almost ceased flowering, for too sudden dryness tells disastrously upon the flowers.

After this, as long a rest as possible was given, keeping dry in December, January, and February, and until growth commenced, but not so dry as to cause the pseudo-bulbs to shrivel. The summer temperature was 65° to 60° at night, 70° to 75° by day, up to 85° or 90° occasionally, and in winter 65° to 70°, down to 60°, or lower in very cold weather.

The reason that I do not now grow Limatodes rosea is, that it does not usually do well in mixed collections of stove plants, but with the culture I have described it never failed to thrive satisfactorily.—G. ABBEY.

THE SIBERIAN PEA TREE.

THIS tribe of hardy yellow-blossoming plants deserves a place in every shrubbery. They are as hardy as Oaks. In

early spring they are covered with a shower of golden-yellow Pea blossoms.

I have two varieties, the arborescens and the Chamlags. I much prefer the latter, both for its miniature tree form and its richer and more profuse bloom. As a dwarf tree either in leaf or flower, I know of no plant which so exactly takes on this tiny form of not above 4 or 5 feet high. Our public grounds should not fail to present these shrubs to the study of the people.

The Chamlags grafted on the arborescens is said to make a very pretty weeper. I have never seen it; but I doubt not, like many plants, it would gain by the stature and force of the more vigorous relative. This saves time and the torment of having every plant bobbed to the flat-topped style, in which the average gardener delights.—(*American Gardener's Monthly*.)

ARDISIA CRENULATA.

THIS is a most appropriate plant for decoration at the present season when Holly berries are scarce. A few plants of the Ardisia in 6-inch pots are valuable for table decoration and for the ornamentation of rooms in general. Larger plants can be placed in the entrance hall, &c., where their scarlet berries and green foliage will produce a charming and seasonable effect.

The plants are easily propagated by cuttings placed in a good bottom heat, but I find a ready way of providing a good stock of plants is to sow the berries in the spring and plunge the pot or pan, as the case may be, in a hotbed or heated pit, never allowing the soil to become dry afterwards. They take a considerable time to germinate. When the seedlings are large enough to handle pot them off singly in small pots in a mixture of peat, loam, leaf soil, and silver sand, and grow them on in a heat of 70° or 75°. The old plants will require to be repotted and grown-on in the above heat so that the berries may be well coloured before autumn, when the plants will last good all the winter if they are accommodated with a greenhouse temperature. The berries can then be picked off, washed and sown, if the stock is required to be increased.—J. A.

NEWSTEAD ABBEY,

THE RESIDENCE OF W. F. WEBB, Esq.

THERE are but few places of such historic interest as the subject of the present notice. Newstead Abbey and the name of Byron, the celebrated poet, are so intimately connected that it is impossible to think of one without the other. Newstead has not only been the residence of a long line of a noble race, but kings, sculptors, poets, statesmen, philosophers, and other great men have done homage to its ancient shrine. Not the least of the long list of worthies who have here found a hospitable home is the great philanthropist, missionary, and discoverer, Dr. David Livingstone, who about ten years ago visited the Abbey, and during his stay wrote his last great work, "Travels on the Zambesi."

Newstead Abbey was founded as a Priory of Black Canons in honour of the Blessed Virgin Mary in 1170 by Henry II. From that time until nearly the middle of the sixteenth century there is little or nothing recorded of its history; no doubt for the simple reason that there was nothing worth recording. However, successive kings were frequently the guests of the abbot—probably having come to enjoy the chase. At the dissolution of the monasteries the Abbey was surrendered to Henry VIII. in July 1539, and the following year it was granted to Sir John Byron, at that time Lieutenant of Sherwood Forest and Constable of Nottingham Castle. After the monks had been forced from this sanctuary, where, according to tradition, the poor, the sick, and the weary traveller had at all times for centuries found an asylum, it was converted into a splendid residence by its noble owner; but the church was suffered to decay. The west end is still a majestic ruin and an elegant specimen of the Early English style of architecture. The house is quite in the antique style, with towers and battlements; it was thoroughly restored about forty-five years ago, having suffered much by the neglect of the two last previous Lords Byron. The Byron family is very ancient, and had large possessions near Rochdale in Lancashire, where they had their principal seat till after the Reformation, when they obtained a grant of Newstead. Charles I. raised Sir John Byron to the peerage in 1643, but as the Byrons were active partisans in the cause of royalty their estates were sequestered by Parliament, but afterwards restored to them by Charles II. From the time of Charles II.

until the accession of William the fifth Lord Byron, commonly called the "wicked Lord," there is nothing of interest to relate of the Abbey or its inmates. The "wicked Lord" died without issue in 1786, when he was succeeded by his grand-nephew, the illustrious poet.

George Gordon Noel Byron, sixth Baron Byron, of Rochdale, was but ten years old when he succeeded to the title and estate, and at that time he was in the Grammar School at Aberdeen, where he received the rudiments of his education. The old lord had permitted the Abbey and grounds to fall into a miserable state of decay and ruin, and he terminated his wild and graceless career almost alone, without a sympathising friend, in the only room in the Abbey which did not admit the wind and the rain.

Soon after this event young Byron's mother sold her effects, which only realised £74 17s. 4d., she having been obliged to endure great pecuniary difficulties in consequence of the licentious habits of her husband, who had fled to the Continent while his only son was still an infant. She and the youthful poet arrived at Newstead, where they took up their abode in the year 1798. The first sight of the dilapidated Abbey made an impression on the mind of Byron that could not be effaced. These impressions continued, and formed the text for some of his famous poems. I will here give one quotation—

"Through thy battlements, Newstead, the hollow winds whistle;
Thou, the hall of my fathers, art gone to decay;
In thy once smiling garden the Hemlock and Thistle
Have choked up the Roses which late bloomed by the way."

Byron came of age on the 22nd of January, 1809. Previous to this he had formed associations which were not in the least degree in harmony with the dignity of his genius and the high position he ought to have taken in society. His companions and associates were of the lowest order, and they indulged in wild and extravagant games. He kept the wolf and bear that he had with him at college at each side the hall door, and when he and his companions were tired of other games, these animals came in for a good share of torture. When he came of age the event was celebrated with a good deal of merry-making. An ox was roasted, and she flowed in a perpetual stream. The Abbey was thrown open, and people flocked from all quarters, but Byron dined on eggs and bacon and ale. Soon after this he set off on his foreign tour, but returned to England in 1811, and published some of those poems which immortalised his name. He subsequently married Miss Milbank Noel, but the union was not productive of happiness, and he soon again bid adieu to the shores of Britain. His pecuniary difficulties increased; and though he had vowed he would never part with the Abbey, yet in 1818 it was sold to his old friend and school-fellow, the late Colonel Wildman, for £100,000. This gentleman set about putting it in thorough repair, and spent a fortune in its restoration. At his death it was bought by its present proprietor, W. F. Webb, Esq. Byron died at Missolonghi, in Greece, on the 19th of April, 1824, at the early age of thirty-six.

Newstead is delightfully situated about six miles south of Mansfield, and eleven from Nottingham. There is a private station on the Midland railway for the use of Mr. Webb, his family, and visitors to the Abbey. As soon as the visitor alights from the station he enters a long avenue of Wellingtonia giganteas; they are planted alternately with Limes and Chestnuts, and in a few years will make a splendid approach to the Abbey. At the end of this avenue, which is about a mile long, we reach the lodge, the entrance to the Newstead demesne. There is nothing special in the appearance of the lodge; it is a plain unpretentious building, wearing an air of comfort, with the walls covered with Roses and Pycnanthas. Another quarter of a mile and we reach the Abbey—

"An old, old monastery once, and now
Still older mansion, of a rich and rare
Mix'd Gothic, such as artists all allow
Few specimens yet left us can compare
Withal: it lies perhaps a little low,
Because the monks preferred a hill behind,
To shelter their devotions from the wind."

The Abbey is charmingly situated and commands some pleasant views of the surrounding landscape. Nearly in front of the mansion there is a spacious lake, thirty acres in extent, supplied by the river Saen. Formerly the borders of the lake were thickly wooded with majestic trees, but the "wicked Lord" cut them down. On either side there is a miniature fort built by the poet's great uncle, and by him mounted with cannon. The "wicked Lord" having been formerly in the navy he called this lake the Mediterranean Sea, and filled it

with miniature craft, and carried on mimic naval fights between his lilliputian fleets. The fort, the nearest to the Abbey, is now converted into a useful cowshed, which is admirably concealed by the fort walls. Near to this spot Mr. Webb has erected commodious stables, built in a style of architecture as near as possible to correspond with that of the Abbey. The fort on the opposite side of the lake is used as a boat house. Byron when at Newstead was very fond of bathing in the lake and rowing on its placid waters, often accompanied by his faithful dog "Boatswain." He would precipitate himself into the water, when his dog would rush after him, and seizing his clothes would drag him ashore. The water escapes from the lake by a cascade, and as it murmurs downwards it becomes picturesque and beautiful. After passing underneath the carriage drive the stream is formed again into another sheet of water near to the pleasure grounds.

We now enter the interior of the grounds, and starting from the ruin of the old church we find our way into what is called the "monk's garden." It is a sort of shrubbery and wilderness, just in the form as it was left by the monks. It consists of cross walks overshadowed by tall Elms and Sycamores, having an undergrowth of Yews and Laurels. Here also is an ancient Clematis, perhaps the oldest in England, clinging to one of the tall trees, with a stem as thick as an ordinary man's body. We emerge out of this grove on to the broad terrace walk, 720 feet long by 15 broad. It runs parallel with the herbaceous border that was laid out by the monks, and never altered in the style of planting. To infuse a little life and freshness into the border a few Roses, Tritonias, and Paeonias have been introduced. The old wall is furnished with Pears planted by Col. Wildman. About half way on the terrace there is a semicircular opening in the wall, from which we catch a glimpse of the Forest Pond. Turning to the right the Eagle or Mirror Pond lies at our feet. It is a splendid sheet of water, so constructed as to represent a mirror. It is about 100 yards long and 50 broad. The grass borders, which represent the frame, are beautifully arranged, and fall down to the water's edge with a regular gradation. The pond is 9 feet deep, with a perpendicular wall all round, and stone steps at each corner, which lead to the bottom. It is fed by springs that rise in the park, and on a fine day the photographic appearance of the Abbey on its placid surface is very beautiful. It was here that the brass eagle was discovered that is now placed in Southwell church.

The grounds in proximity to this pond present a unique appearance. They were designed by Le Nôtre, the celebrated landscape gardener, and are laid out in square beds and walks in the same style as Hampton Court and Versailles. As we wander on this terrace we next reach a flight of rustic steps that lead down to the "Devil's Wood." It was formed by the fifth or "wicked Lord," and is characteristic of the man. The walks are narrow, overshadowed by lofty trees, which give it a sombre aspect. It is in this grove that the twin Beeches were growing on which Byron inscribed his own and his sister's name during his last visit to Newstead in 1814. These two trees were growing with youthful luxuriance at the time Byron carved his name on one of them. The one on which the inscription was made afterwards began to droop, and exhibited symptoms of decay. Mr. Webb, in order to preserve this relic of the poet's fond destruction, had the tree taken down in 1861, and that part containing the inscription was placed in the Abbey under a handsome glass case, along with other Byron relics. The inscription can still be traced as follows:—

"BYRON,
20 SEPTEMBER, 1814.
AUGUSTA."

In this ancient grove are two satyrs "behooved and behorned," male and female, playing with a child, which the "wicked Lord" brought from Italy. They are placed on pedestals where the walks intersect each other, and are such grim-looking objects that the neighbouring peasantry regarded them as "the devils the old lord worshipped." As we pass from under the shadow of the old trees we reach the east terrace. There is the "Devil's Wood" to the right, and on the left a broad border, which forms the boundary of the pleasure grounds. A broad border 6 or 8 feet wide is covered with Ivy, and down the centre is a row of Pinus Douglasii. On the south terrace, which skirts the southern portion of the "Devil's Wood," there is a row of Thujoopsis dolabrata producing a fine effect. Retracing our steps a little we again come to the Mirror Pond above described. Turning to the left there is another fine sheet of water known as the Stew Pond. It is

said that here the monks preserved the fish for their private use. It is in the same state of preservation as it was at the dissolution of the monastery. It is flanked on each side by a row of magnificent ancient Yews. They have been planted for upwards of seven hundred years, and exhibit no signs of decay. At the bottom end of the pond there is a fine bank of *Cotoneaster microphylla*.

At the top of the Stew Pond is the Monks' Well, which is deserving of mention on account of its historic associations. The quality of the water is much esteemed, being singularly clear, sparkling, and of great purity and sweetness. The monks formerly fetched their water from this well, and it is now used in the Abbey. It rises out of the sand rock, and is of the same temperature all the year round. The fernery is situated in a shady portion of the grounds. It was designed by Mrs. Webb about twelve years ago, whose taste in this respect is of the very highest order. It is constructed of stones taken from

the ruins of the old church and Derbyshire tufa. There is a raised embankment with a high mound in the centre. The stones are so arranged as to leave space for Ferns, of which there are many hundreds. On the east front of the Abbey there is the flower garden, laid out in long narrow beds, and in the recesses of the curves are other smaller beds. No doubt in the summer season this garden is bright and gay, but at the time of my visit, the middle of dull November, the beds were cleared of their summer flowers. At the end of this square of grass and just opposite the semi-detached part of the building is the French garden. It is a small space enclosed by a low balustrade, and laid-out in quaint-shaped beds edged with Box in the Louis Quatorze style. Some of the spaces between the Box are filled with different-coloured material, such as white spar, blue slate, red brickdust, &c. This little garden contrasts well with the other part of the grounds, which are mixed in the style they were laid out.

FIG. 2.—BOATSWAIN'S TOMB—NEWSTEAD ABBEY.

At the opposite end of the flower garden and near the ruin of the old church is the monument erected by Byron to the memory of his faithful dog, "Boatswain." Near the tomb stand two grand old Yews and a fine specimen of Cedar of Lebanon. Byron manifested more sorrow at the death of his dog than he did at the death of his mother. The monument stands on a base of six steps, crowned with a lambent flame and panelled in white marble. The monument, the Yews, the Cedar, and the monks' burying ground adjoining, give the spot an air of gloomy solemnity. The monument, of which an engraving accompanies these notes, bears the following inscription on one of the panels:—

"Near this Spot
Are Deposited the Remains of One
Who Possessed Beauty without Vanity,
Strength without Insolence,
Courage without Ferocity,
And all the Virtues of Man without his Vices.
This Praise, which would be no meaning Flattery
If Inscribed over Human Ashes,
Is but a just Tribute to the Memory of
BOATSWAIN, A DOG,
Who was Born at Newstead Abbey, May, 1803,
And Died at Newstead Abbey, Nov. 18, 1808."

On the south front there is a stone terrace with flower beds laid-out and margined with raised stone edgings. From this terrace a broad sweep of grass runs down to the lake. On this

lawn there is another interesting object to the visitor; it is the Byron Oak which was planted by the poet.

On the opposite side of the lake there is a flourishing *Wellingtonia gigantea* planted by Dr. David Livingstone during his lengthened visit to Mr. and Mrs. Webb in 1865-6. The room that Livingstone occupied in the Abbey, and the table that he wrote his last work on, remain just as he left them. There is no room in the Abbey of greater interest to the visitor. Near to the *Wellingtonia* is a *Cedrus atlantica*, planted by Mr. Stanley, whom I heard relate, in the Town Hall, Mansfield, an account of his travels, and "how he found Livingstone."

Passing on to the kitchen gardens, we cross over a small ravine on a rustic bridge that brings us to the American garden. It is a large piece of ground, formerly the wilderness, but now planted with choice *Rhododendrons*. In the spring season they must be beautiful. The American garden is separated from the kitchen garden by a hedge of *Thuja gigantea*. The hedge is 16 or 18 feet high, and has been planted nine years. The kitchen garden is in all respects in character with this ancient and noble place. It is in two compartments, and covers 2½ acres. We first make our way to the vinerias. The first block is 60 feet long and 17 feet wide, in two divisions. The first division had all Black Hamburgs in fine condition. The Grapes were well coloured, the berries of more than

average size, and altogether they were most beautifully finished. One thing I noticed—the Vines at their winter dressing had never had any of the old bark rubbed off, and they were quite free from spider, mildew, and the other ills the Vine is heir to. The second division contained a mixed collection, including Trebbiano, Muscat Hamburg, Clampton Hamburg, Treutham Black, and Duches of Buccleuch, the latter having very small berries; but Mr. Lawrence, the head gardener, informed me that they were intending to destroy it this winter. The next house was just erected. It was 50 feet by 17, and was for late Grapes, such as Lady Downe's and Black Alicante. The border was being made, and from the quality of the material employed, and the skill Mr. Lawrence is able to bring to bear on their culture, superior Grapes may be predicted. Between this house and the before-named vinery there is space left for a range of Peach houses, which are to be erected shortly. We next enter a range of span-roofed houses 76 feet long, in three compartments. The first was used for Melons during the summer. The crop had been excellent, and the sorts grown were Golden Gem, Hybrid Cashmere, and Little Heath; the fruit of the latter weighed from 6 lbs. to 11 lbs. each, and three fruits to a plant. The second compartment was partly devoted to winter Cucumbers, Telegraph and Master's Prolific being the most useful for the purpose. One half of the house was occupied with dinner-table plants. The third part contained a useful selection of plants required for the embellishment of the Abbey. I specially noticed as being worthy of mention a fine selection of Ferns, including *Lomaria gibba*, *Pteris argyrea*—a very fine batch, *Croton*s in great variety, *Begonia*s, *Diefenbachias*, *Poinsettia pulcherrima planifolia*, *Dracaenas*, *Pandanus*, and many other fine-foliage plants, every one useful for the purpose for which they are grown. There was also a good specimen of the curious *Testudinaria elephantipes*, a plant only met with occasionally.

Several lean-to pits are used for forcing flowers and Asparagus, but now filled with *Alternantheras*, *Bouvardia jasminoides*, and *B. Yrelandii*. Another most useful plant for the dinner table, and also for cut flowers, is *Abutilon Ecule de Neige*, which is grown here in large quantity. Several ranges of cold pits were filled with *Echeverias*, and cold frames were full of Lettuces for winter salads. Large breadths of winter vegetables bore the traces of superior culture and good management. There is a broad gravel walk down the centre of the garden. Ribbon borders were planted along each side during the summer, backed up with pyramid Apples and Pears. The gardener's cottage stands at the east corner of the kitchen garden, the back part overlooking the garden, and the front a portion of the pleasure grounds. The walls were mantled with Roses and other climbing plants, and both internally and externally the appearance of comfort was manifest.

I have now finished my journey through this grand old place, and, apart from its Byron associations, it is of great interest and well worthy of a visit at all seasons of the year. The culinary and fruit departments are undergoing a decided improvement, and the plants are in a flourishing condition. Mr. Lawrence has already made his mark on the place, and progress was everywhere apparent.—Q. R.

APPLE ELECTION.

As this is one of my kindred subjects and emanating from such an authority as is Mr. Robson, I believe if a returning officer can be procured there is no danger but the readers of this Journal will have a treat, and a knowledge of the Apple they had not hitherto possessed. It is with very great caution that I offer any suggestion on Mr. Robson's ten classes, still I am inclined to think they are a little too numerous. I would suggest—first, Summer dessert Apples six or eight varieties in order of ripening or marked according to merit; Winter dessert Apples the same, but as they are more numerous, better say twelve kinds or so in order according to merit. Then baking summer or autumn Apples, six, eight, or ten, for keeping and baking qualities, and winter baking Apples after the same manner. This arrangement, if carried out, I believe would give general satisfaction. It would meet both exhibition and utilitarian purposes.—B. G., *Cu. Down*.

POINSETTIA PULCHERRIMA.

At this season of the year the brilliant flowers of *Poinsettia pulcherrima* put all other plants in the shade, but growing it in a pot, as is generally the case, cannot bring it out in its true

character; in a pot a plant produces a few dozen flowers, but on the wall we have 250 or more dazzling heads.

I planted out one plant about fourteen years ago against a back wall, it now covers a space of 24 square yards and has 250 flower heads. Its beauty when the sun is out quite dazzles the eyes, and viewed at a distance it looks like a wall of red fire. This plant seems to do so well that I have to take off yearly about 10 square yards to keep it within the house. The treatment it has is simply to leave it alone, except to keep it clean and to tack the shoots to the wall when growing. The fire is discontinued in May up to September, and from September to May the house is kept at about 55°.

I am told that it is the largest plant in England, whether it is the case I should like to know. Perhaps some of your correspondents will state the sizes of any large plants.—K. DRAPER, *Seaham Hall Gardens*.

MADRESFIELD COURT GRAPE.

This is a magnificent Grape when well grown, but in many places it has been cut out because of that evil propensity—its besetting fault—cracking of the berries just as they begin colouring, which has been fully described in your pages in previous numbers.

I had almost committed the rash act myself of cutting it out, but I am very glad I did not do so now, for it produces each season a heavy crop of Grapes with scarcely a cracked berry. For the first two or three years it behaved very badly with me, nearly every berry having cracked before it was ripe, caused, I have no doubt, by the superabundance of sap, as this Vine inherits great vigour and strength in its young stages, and the berries are very thin-skinned. But I now find that when the Vines become established and carry a good crop, and the atmosphere of the house is kept rather dry when colouring commences, there is very little cause for complaints about cracking, and with the roots entirely under control I consider the results would be more satisfactory in the early stages of the Vine. As a market Grape I consider it a first-class variety, its noble-looking berries always commanding a high price.—J. A., *Hill Grove*.

ROYAL HORTICULTURAL SOCIETY.

The last paragraph of the circular lately issued by the Council of the Royal Horticultural Society proposes guinea fellowships without the right of voting. Judging from the tone of very many letters which I have received, country Fellows will not be satisfied with semi-fellowship. Those who live at a distance who will give a guinea to support a Society they believe to be useful, though they derive little direct good from its shows and meetings, have a right to expect the honour of full fellowship, and will assuredly after a little longer waiting obtain it. The first bid for their support was a guinea associateship, a guinea part-fellowship is now offered, a full fellowship is not far off.

The Council have a hard task before them. There was great difficulty in keeping old and in bringing in new Fellows, even when the South Kensington Garden was well kept up. In its present neglected state the difficulty is greatly increased. Let us hope the neighborhood will generally subscribe, otherwise it is not a pleasant reflection, that however economical the expenditure on the garden may be, as long as it is kept open there will be a charge of some £600 a-year for rates and taxes—a severe tax for this land of now little use if paid out of horticultural money.

I hope that those who believe in guinea fellowships, and who are canvassing their friends through the country will not relax their exertions. A year ago I should have tried to commence this canvass, but was led to believe that the Council were likely to undertake it. Judging from the great number of first-class names collected in two months, a year's work would have given us enough Fellows to make us independent of South Kensington. By this time next year we ought to have completed the necessary number. Strong societies have grown up, starting with supporters less in influence and in number than we already have.

It is now almost necessary to justify the independent course I am taking, though let me say it is no longer I who am advocating guinea fellowships as the one means of making the Society what it should be. I am merely the mouthpiece of very many of the best and most experienced horticulturists of the country of all ranks, who urge me not to let the matter

rest till the guinea fellowship has been accomplished. On a former occasion I had to take independent action, having means of knowing more of the circumstances of the time than some of my friends had. I was so certain that it was for the interest of the Society that the Council of 1873 should be continued in office, that on my own responsibility and at my own expense I circulated the lady Fellows asking for their proxies to support the Council. One hundred and fifty ladies trusted me with their proxies. Twenty more proxies would have carried the vote of confidence and kept in the Council, and this means that the arrangement with the Commissioners on the eve of settlement would have been accomplished, with the result that the Society would now have been free from its debt, free from rent, and with a conditional accession of income, then estimated to amount to £1000, but which I doubt the continuance of. Therefore, having been proved right once, I claim the inference.

I hope that nothing more will be said about turning out the present Council. On more than one occasion there has been great difficulty in finding at all suitable men who would undertake the office. The present work is both unpleasant and thankless. When we get a really good Society with only horticultural work, there will be plenty of first-class men only too glad to serve.—GEORGE F. WILSON.

TOM KING'S GARDEN.

AMONGST the most pleasant episodes connected with the garden are instances of the power of its attractiveness over those to whom at first sight it might be thought to have no charms. We read of martyrs to the love of flowers—those who have lost their lives in the pestilential swamp, and have braved death in the wild beasts' haunts. We are reminded of others who have endangered their existence by sharing their last drop of water with plants which they have been transmitting by land and sea. Such devotion we note with unbounded admiration. It evinces a deep-seated burning love for flowers implanted in the breasts of the votaries of botanical science and horticultural enterprise. Yet such zeal on the part of such men does not evoke nearly so much surprise as a triumph of cultural skill secured by any not known to be intimately associated with the gentle craft; hence the surprise—almost incredulity—which followed when the announcement was made in these columns that the redoubtable athlete, whose popular and familiar name is above quoted, vanquished all comers in the principal class for cut blooms of Chrysanthemums at the late Brixton Show.

When the prize cards were placed on that occasion, and "Mr. Lee, gardener to T. King, Esq." had the foremost position, the Judges not only delivered a just but a popular verdict. Mr. King's blooms were not only decidedly superior, but their owner was esteemed as a good neighbour and supporter of the Society. "Do you know who Mr. King is?" inquired an official. "No," was the reply; "well, then," continued the official, "he is the champion." "Yes, that is clear; someone must be the champion." "Oh! you don't understand me. He is Heenan's victor, and we are proud of him. It's true, honour; but don't say anything." A reporter met at times be faithful to the public, and give the exact words of a speaker; and Mr. King being an admirer of flowers, and keeping a competent gardener to grow them for him, was an "item of news" not to be curtailed in its telling. And now it remains for the dual champion to pay the penalty of his floral fame by permitting the many who are interested in his prowess, and who rejoice in his new honours, to be made acquainted with the garden which yields him, all earnestly hope, solid pleasure—real happiness.

Tulse Hill Lodge is a suburban residence—one of many in its district which speak of well-appointed homes and neat and cherished gardens. At the front of the large light-coloured residence is the little enclosure, containing its few shrubs, its bit of lawn, its miniature flower beds, its shady deciduous trees, and its semicircular carriage drive. On each side of the building stand two sentries—Biches, drooping in silvery gracefulness. Next to the public road is a row of pruned Limes, breaking but not hiding the view from the windows. That is the "little front;" but the garden proper is in the rear—an enclosure perhaps 100 yards in length by 40 in breadth, bounded on both sides by brick walls, and terminating in open meadows. The first half of the long slip is a well-kept lawn containing shrubs and flower beds. Prominent are two large beds of Roses. To the inquiry, "Does Mr. King like

Roses?" was received the reply, "Don't he, though? look at 'em," from one who was charmingly innocent of being "interviewed." One look was enough. There were the Roses planted regularly, staked, labelled, and the surface of the ground well mulched with manure, nourished and protected at this period of the year as all Roses should be which are cared for. Yes, it is certain that Mr. King "likes Roses."

Beyond these Rose beds, and partially separating the lawn from the kitchen garden, are the glass structures. The most prominent is a new span-roofed house about 36 feet long and perhaps 18 feet wide, divided into two compartments—above and greenhouse. A first stage for plants passes round (minus the doorways) this house, and is filled with gay-flowering plants, mostly Primulas. The centre is open, and arranged on the ground level are specimen Camellias in large pots. Some of the plants had recently arrived from the nurseries, one plant having cost five and another four guineas, and the rest were much of the same value. On the roof was being trained *Maréchal Niel* Roses—an excellent idea—the queen of winter, the Camellia, being crowned with the queen of summer, the Rose. Than the varieties of these justly admired flowers none associate better and none are more easy to grow. Any amateur may furnish a house and provide for himself during winter and summer a supply of the finest flowers of earth by growing Camellias and Roses, the former in the body of the house planted out or in large pots, the latter covering the roof, their roots being planted outside after the manner of Vines. The roof covered with Roses is not only not detrimental to the Camellias beneath, but is of the greatest value in affording the shade which is indispensable to the well-being of these plants. Mr. King may well plant other free-growing Roses, especially Teas, which will produce the requisite shade for the Camellias, and almost every day in the year he may have "batten-hole flowers" of the most lovely tints and perfect forms.

In the other compartment are tropical plants. The central bed is mostly occupied with a luxuriant Banana (*Musa Cavendishii*) showing a fine cluster of fruit. When this has ripened it is proposed to proot the plant and devote the pit to ornamental-toliated plants of brighter colours and dwarfier stature. Some of these have been already purchased—*Draenas*, *Crotons*, &c., also Ferns and Orchids. An old house is devoted to utilitarian purposes; but a third, a Cucumber house, is a very useful structure. From three Cucumber plants Mr. Lee last year cut upwards of four hundred fruits, and plants are now being raised for the ensuing season's supply. At one end of this house a few Pineas are plunged in the pit, and on the shelf above Strawberries are being forced.

In the garden are vegetables and fruit trees, the only vacant space in the garden being the lofty shaded north wall. *Morrelle* Cherries would grow admirably here, but they are not liked. Plums, some Pears, Currants, and Roses would also thrive if the walls were limewashed to destroy the moss, tining down the white glare with soot to any tint desired. Were this wall covered the garden would be more complete. A garden such as this and similarly cherished cannot fail to afford healthy exercise to its owner, and the hope cannot be withheld that many gardens are as heartily enjoyed and as well cared for as the garden of our "dual champion," the wide-famed and highly-respected "Tom King." Long may he reign to wear the peaceful emblems on his breast—Roses and Camellias, and

"Place them near his soul,
Not in his heart, indeed, but in his button-hole."

—VISITOR.

GARDENING REMINISCENCES OF THE PAST FIFTY YEARS.

HAVING omitted from my notes on page 552 one of the most important features of the whole period—namely, the hot summer of 1826, I desire to make good that omission.

I verily believe that if its effects on the various garden crops had been as duly chronicled as has been done very often since that time, the year mentioned would have stood out as the most remarkable of the present century. I well remember a field of Barley in a remote district the very reverse to an early one, and yet that crop being shaken with the wind and losing a good deal of corn speedily produced a second crop, which ripened the same year in as good a condition as the first. This is very seldom done even in districts more favoured than the one alluded to, and I do not remember a single case where so good an example occurred. I have seen corn standing out till after Christmas in the same neighbourhood,

and on one occasion witnessed some when a heavy fall of snow broke it down—so much for 1826. Unfortunately my recollection of its effects on garden crops is limited to the remembrance of its being an excellent season for small fruits, which were unusually good in quality. Onions, I think, were also good, but Turnips were poor, and pasturage was also much burnt up, and there were great outlets for water in places where that article was never wanting before, while there were numerous cases of spontaneous combustion, and large districts of moor or forest in Scotland were on fire for weeks, creating great alarm. This, I believe has been repeated since, but not to the extent of 1826. I well remember 1846 being a very dry year, and more recently 1868 and 1870 were both so, but the summer of 1826 has left the greatest impression on my memory as the hottest summer on record.—J. ROSSON.

THE PRESENT WINTER.

THE snow hid from view for a time some of our winter pets. Had last summer's drought something to do with our Christmas Roses being in bloom on St. Thomas's day? I mean *Helleborus niger*. It is an unusual circumstance in our northern region. *Eranthis hyemalis* I have not noted so early in bloom before as this season. The Bear's-foot (*Helleborus foetidus*) was a sight with its bundles of flower heads above the snow, and then drooping down to it. *Helleborus viridis* is on its way. *Daphne Mezereum*, *Jasminum nudiflorum*, *Lanterninus*, and others are indicating the spring time, and are very welcome to us at this season. We do not expect the spring just yet. Christmas day has been on the Monday, and some of our old prognosticators have dark forebodings arising from that circumstance; nevertheless we hope on, and if spared we will work and wait.—OBSERVER.

THE CRACKING OF GRAPES—GRAFTING VINES.

"CRACKING is usually attributed to excess of moisture at the roots." So wrote Mr. Cakin on page 557. It is true, but only just half of the whole truth, the other half being a deficiency of foliage to appropriate the excess of moisture, withdrawing it from the bunches and relieving the berries.

Some varieties of Grapes are more prone to cracking than others, owing to the peculiar brittleness or inelasticity of the skins of the berries, and also the same varieties vary in their liability to crack according to their state at the time of the influx of water. Up to the period of being fully ripe the skins of Grapes are at the full point of distension by the swelling of the interior of the fruit. At that stage they cannot resist further pressure from within by a sudden influx of water being absorbed by the roots. After having become fully ripe there is a perceptible shrinking of the interior of the berries, and their skins also become more tough. This shrinking is occasionally very manifest in the case of Black Hamburghs, especially on old Vines, when the berries lose much of their colour in consequence of it. This loss of colour must have been noticed by many cultivators. In August their Grapes have been quite black, but on hanging until November they have "turned brown"—a simple result of the internal shrinking of the berries, taking, as it were, the backing from the mirror and enabling one, as it were, to look through, quite through, the skin.

Now after this shrinking has taken place Grapes seldom crack—that is, so long as the foliage remains on the Vines; but if the borders become saturated with water before the shrinking, cracking almost certainly follows. Grapes intended to keep well must therefore be ripened early, and particularly if the borders containing the roots cannot be sheltered from the heavy autumn rains. With early ripening and plenty of foliage Madresfield Court Grapes will not crack; but late or imperfect ripening, and a deficiency of foliage at the time of heavy rains, almost certainly leads to rupture of the berries.

Mr. Cakin's Lady Downe's were not ripe, and his Black Hamburghs were ripe before the damp days of autumn set in, hence the failure of the one and the success of the other. He is not alone; several others are in the same position this year in consequence of the exceptional mild and wet autumn, which could not have been anticipated. No doubt the linewash was left on the glass too long and aggravated the evil complained of.

As to the substitution of another white Grape for the White Frontignan I should have Buckland Sweetwater. If the Vines are young and the border comparatively new I should plant a

young Vine, but if old I should graft or inerech on one of the older Vines. It is not of much use planting a young Vine in an old Vine border. I have had no experience of the White Frontignan as a stock for other varieties, but I know the Black Hamburgh is an excellent stock for Buckland Sweetwater. A Black Hamburgh stem and roots will support two rods as well as one. Perhaps the safest and simplest form of grafting is bottle-grafting. Take grafts now of stout well-ripened wood. Keep them fresh until the stocks have commenced growing in the spring; then take a deep slice 6 inches long from the middle portion of the graft and a corresponding slice from the stock, and fit them together, tying with tape and surrounding with moss. Place the lower end of the graft or scion in a large bottle of water, filling up the bottle as the water wastes, say until July, when the union will be complete and the graft will have grown half way up the house.—A RETIRED GARDENER.

THE OLD MARKET GARDENS AND NURSERIES OF LONDON.—No. 14.

THOSE individuals who have been acquainted with the suburbs of London for the last forty or fifty years have noticed, if observant persons, a peculiar order of succession in the occupancy of the land. In Georgian days districts now covered thickly with houses were more than half rural, and the farmers cultivated Wheat, while herds of good-conditioned cattle grazed on the grassy fields. After a time the cattle began diminishing in number; and though many cows were still pastured, the farmers found it to their advantage to plough up some of the fields, and send from them Potatoes, Turnips, and Cabbages to the London markets. By an easy transition the whole of the land thus disposable came into the hands of professed market gardeners, and even the cows had to withdraw, to be immured in unwholesome houses and sheds, for the best (or worst) part of their lives. The next change would be, that the demand for building sites seriously trenching on the garden ground, the grower of vegetables removed farther away, and gave place to the nurseryman, who generally needs less space. He, devoting himself to fruits and flowers, has most of his plants under glass, and only a few in the open ground at London, drawing fresh supplies from orchards and plantations out in the purer air of the country. In some suburbs, however, even nursery gardens disappear, and only the "florist" as he calls himself survives, with no land at all attached to his place of business, except enough to admit of the erection of one conservatory for the temporary accommodation of the plants he sells off rapidly. Occasionally, as in parts of Westminster and Balgravia, so fast has been the growth of London that this succession has been broken in upon, and land has passed at once from the market gardener to the builder, leaving scarcely a nurseryman or florist behind to tell the tale of other days. The like circumstance is to be recorded of Islington and some northern suburbs.

There is a largish district of London, situate on the Middlesex side of the Thames, within a bend of that river, and bounded on the north by the West End parks and squares, which is notable as having been early occupied by market gardeners. Belonging to the city of Westminster it was originally in the parishes of St. Martin-in-the-Fields and St. Margaret's; subsequently by change of boundary a considerable section has been transferred to St. George's, Hanover Square. Centuries ago much of this land was overflowed at certain states of the tide; it is even yet, despite the large deposits which have been made upon it, below the level of the stream. When it first came under cultivation, indeed, the earth had the character of peat or bog, but it was partially drained by numerous little cuts or streamlets. This region we now know as Millbank and Thames Bank, and some part of it constitutes South Balgravia, with, as must be acknowledged, not at all a desirable subsoil. There are many open places in the district, thickly as it is studded with houses, and here and there factories, but it is difficult to realise that it was formerly fields, gardens, and commons; for Tothill Fields, bordering on St. James's Park and formerly extending towards Millbank, was grazed on for centuries by cattle, and city herbalists gathered Coltsfoot with other wild plants used as medicaments on its sloping banks; and from one of these, which rose to the height of a hill and served as a watchman's station, it had its name of Tot or Tothill (*To tot*, was to look out from an elevation over the lower country). Millbank doubtless had its designation from an ancient mill, which was a landmark to those

moving up and down the river; and much of Westminster proper was garden ground attached to houses down to Stuart times; not to speak of the Spring Gardens, open to the public, and the well-laid-out gardens of Whitehall Palace, though then St. James's Park was wood and swamp. Reminiscences of the past remain in such names as "Gardeners' Row," in Vine Street—for Westminster once had some choice Vines—and in Orchard Street, supposed to mark the situation of the old orchard belonging to the monastery. (The name "orchard," however, may be misleading in a London locality, thus Orchard Street, Portman Square, and is really derived from an estate in Somersetshire.) One speculates as one walks, Where was the garden belonging to Mrs. Cope, the plant from which were bought by the Apothecaries' Company in 1676, and removed to their Chelsea establishment? Was she a pioneer nurseryman—nursery-woman I should say? Vain it is also to seek for traces of Switzer, whose name bespeaks his foreign extraction, and who advertised that he might be seen at the "Sign of the Flower-pot over against the Court of Common Pleas," and at his gardens on Millbank. He was a man of some importance, at least, in his circle of friends, the author of "Iconographia Rustica," and designed various gardens in England and Ireland.

Of the other occupants of garden ground at Millbank during the eighteenth century there is nothing of importance ascertainable, but soon after George III. came to the throne they began to give place to houses and factories, and a huge prison or house of correction was erected on one plot close to the river. A view of Westminster, taken from Millbank in 1807 for publication in "Smith's Antiquities" of that place, is taken from a wood yard, and between this and the streets surrounding the Abbey is shown a patch of garden ground on which men and women are gathering produce. I surmise this is intended to represent a market garden, probably occupying a portion of the land once attached to the old mansion called Peterborough House. In that unsavoury locality, the Horseferry Road, there was a market garden at the commencement of the present century, where there is now a gas factory, this garden being agreeably shaded with rows of Poplars and Elms; and at an earlier date still, being a place of popular resort for tea-drinking and the like, not far distant from that remarkable district "Palmer's Village," which served to furnish some years ago, a sensational article descriptive of a Westminster slum. An old resident remembers a small market garden which would be on the line, I suppose, of the modern Victoria Street; for after Millbank was built on there was much open ground at Pimlico, where Mr. Elliot the brewer had an enclosed space which was actually called a park.

And here, before we proceed further in our exploration of the Pimlico district, let me remind the reader that the first nurseryman in Pimlico was King James I. He had an idea that the culture of silk could be made highly profitable in England, so he obtained from the continent many thousands of young Mulberry trees, and in 1609 spent about a thousand pounds in planting a nursery of Mulberry trees at Pimlico, on the site of Buckingham Palace or its grounds. He also distributed Mulberry plants in various districts of England, and it would appear that at this Pimlico establishment, which was called the "Mulberry Garden," the experiment had a measure of success. We have no weather registers of so old a date as the Stuart period; but some think that as the average English winter was far colder then than it is now, the summers were warmer and more equable, allowing under certain conditions of the breeding of silkworms in the open air. Charles I. in 1629 granted by letters patent to Lord Aston the custody of "the gardens, Mulberry trees, and silkworms near St. James's," for his own and his son's life; the Civil War and its troubles probably put an end to this little arrangement. Are there now any descendants of those Mulberries surviving? Pimlico was open enough in that day; and long subsequently its common, locally known as the "Five Fields," and to which reference has been made in a previous paper, was partially cultivated by Chelsea market gardeners, though more of the garden land lay in the vicinity of the Neat houses. Many living in the neighbourhood can remember when nearly all South Belgravia was fields; and as a proof how sparingly the houses were scattered in this neighbourhood and in the opposite districts of Surrey, an old gentleman has been heard to relate how he had, when out for a morning walk, stood on a hill at Norwood and seen by a glass his children playing in his garden at Pimlico. There are traditions, too, of nightingales having been heard singing in shrubberies at Knightsbridge.

But the story of the Neat houses, so far as the horticultural history of the locality is concerned, goes back to Strype's time, whose entry on the matter is as follows:—"These houses are seated on the banks of the Thames, and inhabited by gardeners, the place being of note for the supplying London and Westminster markets with Asparagus, Artichokes, Cauliflowers, Muskmelons, and the like useful things, which by reason of their keeping the ground so rich by dunging it, doth make their crops very forward to their great profit." The dwellings, however, did not receive their appellation from their neatness or elegance, but because they stood on a part of the manor of Neyte or Neate, belonging to the Abbey lands.* And a later chronicler remarks that this land, originally under water, was kept in high fertility by quantities of stable dung to the amount of sixty cartloads an acre. Liquorice is also stated to have been grown here to some extent. When Lysons wrote towards the close of the century, market gardening was already on the decline in this district, from, as I should conjecture, an increase of market gardeners in more favourable spots. But the statement must surely be erroneous that there was ever as much as two hundred acres of land under cultivation, even if Millbank be joined with the Neat district.

When the last market gardener withdrew from South Belgravia I am unable to say positively, but I believe there were still a few fields there in 1849 and 1850. An entomologist formerly resident in Belgrave Place has told me how he obtained caterpillars of the common white butterflies, for the sake of breeding varieties, from the gardeners across the Grosvenor Canal opposite his house; this would have been about the year 1840. An old house called the White House, once frequented by anglers, overlooking the Thames, long since removed, has been conjectured to mark the position of some one of the Neat houses, but this is doubtful. The ground acquired by Lord Ranelagh when he built his mansion in 1690, and called in old maps "Thames Shot" and "Arnold's Mead," amounting altogether to more than twenty acres, was adjoining or belonging to the Neat estate. "Ebury" is a familiar name in Pimlico to this hour—a reminiscence of an old manor called Eybury, from its watery character, ere the land was under drainage; it is needful, however, to show that "Avery," also occurring here, is no corruption of the former name, but descends from the Avery family, who for generations had a farm in Pimlico. Avery Farm was afterwards subdivided into two or three market gardens. Where St. Barnabas College now stands was, at the close of last century, the Orange Tavern and Tea-garden, and when that establishment failed the ground was still need to produce vegetables for the market. Near this spot was the garden belonging to Mr. Dennis, who removed to the Kioq's Road, Chelsea, near Cremorne, some thirty years ago, I think. He was a nurseryman as well as a market gardener, and his name is associated with one or two novelties.

The departure of the nursery which once occupied the centre of a small square in Pimlico, called Ebury Square, was the final knell of the nurseries in the district; this took place about 1859. The last occupier, I believe, was named Prior; before him Mr. Larkham, and his predecessor Mr. Brown, carries the history back as far as I can trace it. Possibly before the square was built the garden ground was more extensive.—C.

OUR BORDER FLOWERS—GUNNERAS.

PLANTS, like old robes, are liable either to be cast to one side, or stored away for use at another and more convenient time. The world is being sought through for novelties in the way of plants, but it is astonishing how soon a new introduction loses its attractions and is counted as "old." Now that new places are springing up on every side many old plants are also being sought after, and when found they secure favour. But it must be remembered that border flowers require looking after, or many of them may take their departure without giving us any warning.

The family of Gunnera is small. *G. perperna* is figured in the "Botanical Magazine," 2376, and is said to have been introduced in 1688, but I fear that it is among the plants of the past. It is a native of the Cape of Good Hope, yet we have come among us of more recent introduction. From South Brazil we have *Gunnera manicata*, having leaves which with a little support might afford our youngsters a useful shade in the shape of a parasol. *G. esoba* is perhaps

* We believe the Neat houses were so called because the dairymen had their cow houses there. "Neat" means all kinds of horned cattle.—Eds.

the most generally known of the family; it has a Rhenish-like appearance, and by some the acrid stalks are eaten. The Gunners are what are termed coarse-growing plants, and to some tastes may be unsightly, but where change and diversity of foliage are required in large borders, shrubberies, and out-of-the-way places they are antible plants. They are increased by division in spring, and if they have the same treatment afforded that is given to Rhenish there need be no fear of their not succeeding. Large clumps in woodland walks and by the margins of water are very bold and imposing.—*VERITAS.*

FLOWERING PELARGONIUMS IN WINTER.

Our collection of Geraniums has proved of so much value to us since the beginning of October until now, and apparently will continue equally valuable for some time yet, that we cannot refrain from recalling attention to the qualities the Geranium possesses as a winter flowerer. Until the end of November Geraniums of different shades of colour, from pure white to the darkest maroon crimson, were almost the only flowering plants on the side stages of the conservatory; a few Epacris and foliage plants being intermixed to avoid tameness in the arrangements. We have now a goodly number of Chinese Primroses, the earliest Cyclamens, Roman Hyacinths, &c., to take the place of the earliest flowered Geraniums; but those still in flower attract most attention from visitors. One of the vinerias has also been nearly filled with plants more or less in flower during the above-mentioned period, so that we have been at no loss for plenty of flowers of the brightest kind. We have a pretty good collection of Chrysanthemums in flower, mostly in a late Peach house, and very interesting they are; but as long as the Geraniums are to the fore, with many of them with trusses of bloom as large as the individual blooms of the Chrysanthemums, the latter hold only a secondary position with us. Fine as they are as plants for decorating conservatories and show houses, they are probably even more useful when cut for mixing with other flowers in epergnes, glasses for rooms, and for dinner-table arrangements. At the present time Chrysanthemums and Geraniums form the staple of the cut flowers we use; both kinds are arranged so as to stand entirely free from other flowers, so that not only are the beauties of the flowers thoroughly open to view, but the time they last fresh in a cut state is wonderfully extended. Large trusses we employ mostly singly in glasses, merely adding a Geranium leaf or a spray of Fern as a setting. From about the 25th of November I find the pips are less subject to damp-off than they are for a month before that date; in fact, if the plants merely have sufficient water to keep them healthy, a full open truss may be expected to keep in good condition for nearly a month, and two or three weeks longer in a cut state if not allowed to remain too long on the plant before cutting.

As already mentioned, one of the vinerias has been nearly filled with plants; it is a late Hamburg house, and up to this date there are still leaves on the Vines and some fruit hanging. Under these disadvantages the Geraniums have not only bloomed well, but flower trusses are still forming on many of the plants and opening every day. We may also note that some of the newer kinds which were planted out on trial and potted into 5 and 6-inch pots in the beginning of October, have done us good service, some of the finest trusses lately developed being on these plants. Every individual plant is allowed clear standing room, and arranged on the stages without raising the plants higher than they have grown. Every plant is thus directly under the eye, and no harm is done them from overcrowding—a point of importance.

Now as to varieties. We have added about seventy varieties to our collection during the past year, and have been tempted to try a few more of the new sorts this next spring. After that we intend to select and keep only the best; but this is a difficult thing to do unless one is thoroughly imbued with the spirit of the *Auricula fancier* Alphonse Karr paints so graphically. Though one may not have such perfect-shaped pips as it might have, still the truss may be fine or the colour unique; or though the truss may be a long way off the "baby's head" standard, yet the form of the pips or freeness in blooming may hold one's hand from utterly destroying those found wanting in other respects. The varieties we name below we can thoroughly recommend as good for the purpose of supplying blooms during the dreariest months of the year. Vesuvius and other small-trussing varieties we have found wanting; those that have given most satisfaction in all respects are the larger-trussing kinds, some of the newer sorts being re-

markably free flowerers. It is somewhat curious that the darkest crimson flowers and the purple-shaded varieties are the best late-blooming kinds; the deep-shaded, large-trussed pinks are the kinds least adapted for very late work; light pinks, scarlets, and salmon-shaded flowers being useful, but not so good as those possessed of the first-mentioned shades of colour. Of the dark crimson, purple, and cherry-shaded flowers the following have been best: Earl Manvers, Mrs. Haieh, Brutus, Jessica, Colonel Holden, General Outram, Diana (the most useful), Purple Prince, John Fellowes. From amongst the scarlet shades the following are recommended: A. F. Barron, Mrs. J. George, Sir John Moore. Some of the small-trussed kinds with scarlet flowers, though not so showy, are good for cutting from and save the others: we note Mrs. Learcroft, Mrs. Whiteley, De Leseeps, and Richard Dean as good, the first three more especially. Princess of Wales is much liked at this season; it is rosy-scarlet in colour. Our best pink is still Master Christmas. Mrs. Quilter is also good for late flowering. Metalf is also a good sort; but the best large-trussed varieties, as previously noted, do not succeed. Polly King, a salmon-shaded flower, is one of the very best. Rev. S. Hay is a good companion flower. White Perfection is still a good white-flowering kind. White Swan proves a late bloomer and very pure, but the trusses are very small. Of the above, Earl Manvers, Diana, Sir John Moore, and Princess of Wales should be grown in quantity, as they will keep on flowering when all other kinds we know are over.—E. P. BROTHERTON (in *The Gardener*).

NOTES ON VILLA AND SUBURBAN GARDENING.

KITCHEN GARDEN.—With the beginning of the new year, if the weather should prove drier, gardening operations will begin to revive. Not only will it be necessary to sow seeds for the early outdoor crops, but I fear that that can be done much lost time will have to be made up on account of past delay through the continued wet. About this neighborhood amateur are beginning to be adroit about their soil not being trampled, but then I consider it is much better not to interfere with it while so fully charged with water. When it is convenient to work it I advise its being ridged instead of flat-digging it. Ridging not only exposes the soil more, but water will drain and dry from it better than if the surface is left level. The plan of leaving the digging of the soil till the time of planting is fast being given up, even by the humble cottager. The importance of preparing the soil beforehand is now generally admitted. The farmers about here, whose land is highly rented, find it profitable to adopt a system of deeper cultivation than once prevailed. The same system may be applied to a garden; therefore as soon as dry enough dig the soil deeply, and if manure is to be added let it be much more decomposed than is usually the case when digging is done in the autumn. The soil is so beaten down with heavy rains that it should, when a little dry on the surface, be lightly stirred up between young growing crops.

I advise the sowing now of Early Mazagan or Early Longpod Beans, also Peas, on a border exposed to the south. Sutton's Ring-leader, Kentish Invicta, Laxton's Alpha, and William I. are good early Peas. The latter is the strongest grower and is a good cropper. The seed should be sown in shallow drills at this time, or it is liable to rot. Those who desire early Carrots should sow seed in a frame at once. A deep frame is necessary so that the dung may be put inside, and as it is to be deeply covered with soil it need not be previously heated so much as if for Cucumbers. I generally make a sowing at this time in rows as near the glass as I can make, between the Carrot rows of Radishes. These come off in time to allow the Carrots the necessary room. Continue to place Asparagus roots in frames if a accession is wanted. On the surface of this I also sow Radishes. Both the above vegetables require gentle heat.

The ground allotted for Onions must, if it has been previously prepared, be forked over again the first opportunity. While the weather is mild plenty of air must be admitted to Cauliflowers in hand-lights and frames, for if they grow too large before the time for planting-out the check caused by that operation turns them into "buttons." Lettuces at the fronts of walls must be looked after, as slugs are very busy, and if a little lime and soot is applied occasionally to the surface, and pointed-in it will be beneficial. Prepare all kinds of soils and manures likely to be wanted when fine weather comes, and the work at that busy period will be expedited.

FRUIT GARDEN.—Pruning Vines would appear to be one of the most difficult operations for an amateur to do well, not so much perhaps from a want of knowledge, but from a fear of using the knife too freely. I notice in many small houses that too many rods are grown. In some cases they are not much more than a foot apart. Now the Vine is very accommodating, but it can be overcrowded. The rods ought to be 3 feet apart, so that

the shoots can become strong and the foliage large and healthy; then the weight of Grapes will be heavier and the fruit finer than if the canes were trained closely together. I recently observed Vines which had been so much crowded that some of the rods though only four or five years old had gone blind half the way up, though vigorous for the first year or two. The want of light and air were the causes of their producing weak shoots and imperfectly ripened wood, which could not break into growth sufficiently strong to continue from year to year. Therefore thin out the rods freely, and if pruned on the spur system the buds close to the main rod will be plump and able to carry a bunch successively, and if grown on the long-rod system there is a capital chance of the canes being well ripened and the buds prominent, so that they can always be depended on for a crop. As to cleaning the Vines after pruning, I agree with only taking off the loose bark, and not picking and scraping till the fresh bark is exposed to view, for I am of opinion that while the bark adheres to the Vine it is still of essential service to it.—THOMAS RECORD.

DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

KITCHEN GARDEN.

The continued wet weather has rendered it impossible to work with profit, especially on clay soil. On our light garden soil we have been enabled to complete the pruning of Apple, Pear, Plum, and Cherry trees. Pyramids and bushes have a great tendency to become crowded through continued summer-pruning or pinching of the growing shoots; and if the trees are planted closely together, as they are in some gardens, the evil is apparent in weak unripened wood, and fruit of inferior quality. It requires some degree of courage on the part of the inexperienced to attack his trees with a pruning knife for the small branches, and a hand saw for those of larger growth; but unless this is done sometimes, it is not possible to attain success. Amateurs who are fond of fruit culture, and many are, would do well to take a lesson from an experienced gardener on pruning their small bush and pyramid trees. A few minutes spent in looking at a man proficient in his work would do more to impress the principles of pruning on the mind than pages of instructions. In thinning-out the old branches, it is necessary to remove those that cross others, and it is also desirable to avoid pruning the main branches, so that they become too weak to support their load of fruit; many persons prune the main branches so that they become long cordons of closely-out spurs. They cut the young wood closely back, and annually just shorten the leader. When this goes on for a number of years it will be necessary to cut back the branches, and to encourage them to branch out laterally.

In shallow light soils, or where there is a bad subsoil, it is very desirable to encourage the formation of surface roots, and this is best done by mulching over them with short litter. In some cases it is also best not to fork amongst the roots at all; but if digging is desirable, it must be done in a careful manner. When the surface is loose the roots have the greatest tendency to work into the subsoil, and if the operation of forking the ground is carelessly performed many of the surface roots are broken off.

The late Mr. Robert Fish used to complain much about the injury to his fruit trees from the attacks of small birds, tomits and bullfinches especially. Except the homely sparrow, and a few blackbirds, no other feathered friends visit our garden, and in severe frosts a few Gooseberry and Currant buds are eaten, but other fruits are not touched. Mr. Fish used to syringe his trees with lime whitewash until all the branches and buds were covered with a white coating. He preferred this to mixing the lime with soot, and it used to stick to the trees, even after heavy rains. It also effectually prevented the birds from eating the buds.

MUSHROOM HOUSE.

Materials which are being prepared for new beds must be kept dry during preparation. An airy shed is the best place. There is no danger of the manure becoming too dry. It ought to be thrown up into a heap or ridge for a few days, but when sufficiently heated it should be turned every day, and when dry enough it may be used. Those who are not able to obtain large quantities of stable manure at once, but who must be content with dribbles, ought to spread it out on the floor of a shed until sufficient has been obtained, and always keeping it in the dry. Another plan that has been successfully tried is to place the manure in the bed as it is obtained, and this is certainly the most convenient, for very few gardens are overdone with shed room. It is best to place a thin layer in the bottom of the bed, heating it down firmly, and adding from half an inch to an inch in depth every day. When sufficient depth has been obtained the bed may be spawnd—that is, if the temperature is not likely to rise above 60°, and in a week or so after spawning the surfacing of loam may be added in the usual way. When beds are made up in this way the largest proportion of the properties of the

manure is retained, its valuable constituents not being driven off by excessive heat.

CUCUMBER HOUSE.

Seeds have been sown to produce plants in succession to those which have been in bearing for some time. They are sown in a little bottom heat, but this can only be obtained by keeping the pots at a considerable distance from the glass. As soon, therefore, as the seed leaves are formed the pots will be placed on a shelf near the glass, and in a few days afterwards each plant will be potted separately in a small pot. We like to pot the young plants well down into the pot, burying the stem quite to the seed leaves. When the soil is sufficiently moist at the time of sowing the seeds, it will not be necessary to water it until the plants are potted-off; indeed it is dangerous to the plants to water them at that stage, causing many of them to damp off. After potting them singly this will not likely occur. The temperature ought to be from 60° to 65°.

GREENHOUSE AND CONSERVATORY.

Great care is necessary now to prevent plants and flowers from being injured by damp. It will be necessary to warm the hot-water pipes to expel moisture, but the fires must only be lighted when the ventilators can be opened, and that is when the air is dry and light outside. The frequent thick foggy weather about London tells upon the plants, and it is much better at such a time to keep all the ventilators shut. At such a time the fires ought not to be lighted unless, which is sometimes the case, intense frost is accompanied by damp. When other work is not pressing is a good time to tie down and train into position the growths of Cinerarias, and stage and fancy Pelargoniums, if they are intended for specimen plants. If this operation is delayed the growths become stiff, and they are liable to snap off at the joints. It is best to lay the foundation early and then work upon it as opportunity offers, tying down the growths just a little at a time. There ought not to be any decaying or spotted leaves; if there are it is a sign that the plants are not in very healthy condition; indeed, if it is a case of spot it is certain that the functions of the plants are very much deranged. One cause of spot is deficient drainage, aggravated by too much water at the dullest period of the year, or cold hard water having been used instead of rain water rather warmer than the temperature of the house. Fancy Geraniums require a much lighter compost than the stage varieties, but all of them must be grown in well-drained pots, and with judicious ventilation and watering there is little danger of the plants suffering from damp or any other cause.

We have been inserting cuttings of the different varieties and types of Chrysanthemum. The sooner this work is done the better, both for growing large flowers and specimen plants. It is necessary to be very careful that the plants receive no check to their growth, else they will not unlikely start into premature flower. We have inserted at this time of the year cuttings of the Pom-pom section, and they have made splendid specimens. We have done so on another occasion, and every plant has started into flower by May. It is well to put in cuttings in February or March in case the early-rooted plants should run into flower.

FLOWER GARDEN.

Attention must be given to hedging plants. Calceolarias winter best in cold frames, either behind a north wall or the frame placed with its back to the south. Ours were put in about the end of October and have required no attention since, as the frame is on the north side of a wall, and the boxes in which the cuttings are do not require much water. We have commenced potting-off and boxing zonal Pelargoniums of the different sections, beginning with the variegated and bicolors. They do not require much water in winter, and it is tricolor to allow the soil to become quite dry before applying water; the plants should also be in a dry airy place. Under such circumstances a few degrees of frost will not injure them. Verbenas are much subject to the attacks of green fly, red spider, and thrips. Dipping them in the solution recommended a fortnight ago for *Azalea* will destroy all these insects. Fumigating with tobacco smoke occasionally is a very good practice for keeping the plants clean. The surface soil of the pots should be occasionally stirred with a pointed stick to prevent green mould from forming. Weeds and decaying leaves to be removed. Time can be afforded for such work at this season when the weather is rough or the ground frost-bound out of doors.

Auriculas in frames continue losing their foliage, and it must be removed as it decays to prevent spreading decay to the vital parts of the plants. Damp is very destructive to the plants, and it is important to see that the lights are watertight before the winter sets in. The soil just requires sufficient water at this time to prevent the leaves from flagging. The lights are removed every day in fine weather, but in account should the plants be exposed to cold winds or severe frost.

Carnations and Picotees must also be kept clean. The first trace of green fly should be the signal to fumigate the frames with tobacco smoke. Some growers complain of the prevalence of spot on the leaves. This is caused by damp. Mr. G. Rudd of Bradford, who, like many more ardent amateurs, grows his

plants under unfavourable circumstances, finds that he can keep them free from rot by placing the pots on boards and raising the frame a little off the ground, thus allowing the air to circulate freely amongst the plants night and day. He says they do not suffer at all (thing from frost if the soil is as it ought to be—moderately dry. Pinks are looking very healthy in the beds, but the ground is spongy with so much wet, and frosty weather would throw many plants out of the ground. Dahlias should now be examined, and all decaying portions of the tubers be removed.—J. DOUGLAS.

TRADE CATALOGUES RECEIVED.

Charles Turner, Royal Nurseries, Slough.—*Descriptive List of New Dahlias.*

S. Dixon & Co., 34, Moorgate Street, London, and Amburst Nurseries, Acton.—*Select List of Vegetable and Flower Seeds, Potatoes, &c.*

B. S. Williams, Victoria and Paradise Nurseries, Upper Holloway, London, N.—*Descriptive Catalogue of Flower, Vegetable, and Agricultural Seeds.*

Editha Boot, Norwich.—*Illustrated Guide for Amateur Gardeners and General Seed Catalogue.*

William Rynsey, Joylands Nurseries, Waltham Cross, London.—*Catalogue of Select Garden and Farm Seeds, Potatoes, &c.*

Francis & Arthur Dixon & Sons, 105, Eastgate Street, Chester.—*Catalogue of Vegetable and Flower Seeds, &c.*

Little & Ballantyne, Knowlhill Nurseries, Carlisle.—*Catalogue of Stove and Greenhouse Plants, Roses, Rhododendrons, &c.*

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

Books (Retailer).—"Thompson's Gardeners' Assistant" contains in one volume all that you require. (H. Burbank).—Any bookseller can obtain the book for you and tell you the price.

PLANTS FOR GLASS CASE IN WINDOW (Noveboracian).—As such plants as *Primula sinensis* are killed by frost we advise you to grow some Dutch bulbs, such as *Hyacinths, Crocus, Tulips, Narcissus, &c.*, and fill the case with greenhouse plants during the summer and autumn months.

EVERGREENS FOR BULWARK EXPERIMENT (E.).—We would advise planting it with Spruce and Scotch Fir, with an undergrowth of common Laurels. Or if you felt inclined for more expensive trees there are many coniferous trees adapted for your purpose. *Ficus tigris* grows rapidly and forms a dense screen, but it is not sufficiently hardy in exposed places. Your soil is a good one for fruit trees, and if they have become covered with moss the probable cause is that the grounds are not well drained; this might also account for the bark cracking. The roots may have gone deep in the subsoil, and lifting them out of this might check the growth of the moss. Try draining if the soil is wet.

MILDEW ON VINES (E. S.).—We had a case similar to yours some years ago, when sulphur failed to keep the parasite in check. The roots had worked into an unsuitable subsoil, and when they were lifted out, and some rot had been placed round them the mildew disappeared. You may try this if you find the roots are not in good condition.

FORCING STRAWBERRIES (Captain Lyon).—If you have good plants of Keen's Seedling in the open ground from young runners last season, lift them at once and put in 6 or 8 in pots, and place the pots in a cold frame or cool house. They will require very little forcing to have fruit ripe by the time you name. We have gathered British Queen from the open ground about the middle of June. Young plants will produce most runners next season if they are potted now and grown-on in pots to be planted out in April. You might put the Keen's Seedling in a forcing house about the middle of April.

HYACINTHS FAILING (Idem).—We cannot account for the *Hyacinths* doing badly unless the bulbs were of inferior quality. As the pots are well filled with roots it could not be the soil that is at fault. The treatment has been right.

LIST OF EVERGREEN SHRUBS AND HYBRID RHODODENDRONS (J. C. H.).—*Rhododendron*: Azura, Albus, Alba, Arbus, Arbus, Eliza, Rose-galeum, Baron Oay, Barclayanna, Blandiana, Comense Salvi, Comenseum, Chianoides, Elfrida, Frederick Waterer, H. W. Sargent, John Waterer, Joseph Whitworth, Mionie, Schiller, The Queen, Zippoo Sabih, Twarditi and Yandoo. *Evergreen Shrubs*: *Juniperus chinensis*, English Yew, the common and Portugal Laurel, Sweet Bay, Aucuba japonica in variety, varieties of Box and Privet, Phillyrea, Mahonia, and Holly.

RUSSIAN TRANSPARENT APPLE (H. S.).—We hope shortly to be able to give the information you desire.

KEEPING ONIONS (Slapshill).—Your Onions were probably exposed to rain after they were harvested, which would much affect their keeping. The very best method of keeping Onions is to string them in bunches and hang them in an open lodge where they are dry yet fully exposed to air and frost.

RHODODENDRON LAYERS (J. C.).—Cut the branches immediately and plant on the first favourable opportunity. You may be glad to learn that any *Rhododendron* having a good ball of roots and soil may be transplanted in perfect safety at any period of the year.

NOTICE TO LEAVE (A Constant Reader).—If a gardener lives in his employer's cottage, has his wages paid weekly, and the cottage is considered part of the gardener's wages, his employer can turn him out after a week's notice.

SELECTION OF STRAWBERRIES (Amateur, Norwich).—We published very full selections in our numbers 608 and 610.

Newtown Pipers (J. E.).—Fruit medium-sized, roundish, broadest at the base, with broad obscure ribs extending to the apex, which give it a peculiarity in its outline. Skin at first dull green, but changing as it ripens to a fine olive green or greenish yellow, with a reddish brown tinge next the sun, and dotted a l over with small grey russet dots. Eye small and closed, set in a small and rather shallow basin. Stalk half an inch long, slender, and inserted all its length in a deep narrow furrow lined with delicate russet, which extends over a portion of the base. Flesh yellowish white tinged with green, firm, crisp, very juicy, with a rich and highly aromatic flavour. A dessert Apple which, when in perfection, is not to be surpassed. It is in use from December to April. This description is taken from an imported specimen it most not be expected that fruit grown in this country will attain the same perfection, for like most of the best American Apples it does not succeed in this climate. Even with the protection of a wall and in the most favourable situation it does not possess that peculiar rich aroma which characterises the one imported from America.

Mrs. POLLOCK GRANITE (P. Bourke).—The lady in whose honour it was named lived, perhaps lives, somewhere near Belfast. There is no later edition of the dictionary.

WATERING (Mr. Bodkin).—Water from a metal tank is not injurious to plants. No one could advise decidedly about diluting liquid manure not knowing what it is. The draining from a stable may have seven times its bulk of water added.

ANTI-MILDEW LIGNON (J. Mackenzie).—The ammonia is the most potent ingredient, but some of the saline constituents are destroyers of fungi.

COLLECTING SPECIMENS (C. F. W.).—The most courteous and most effectual way is to write for permission.

BULBS IN BEDS (Alpha).—Your bulbs by the addition of 4 to 6 inches of fresh soil will be 7 to 9 inches beneath the surface. They will be much later in flowering by the additional soil, but we do not think they will be materially injured, the bulbs being taken up after flowering. Any small plants of an evergreen character will run over and become lunched, and in a majority of instances be ruined. We should remove the soil as once, as it can do no good even to the bulbs, and will certainly injure herbaceous plants.

NAMES OF FRUITS (A Subscriber).—1, Black Hamburg; 2, judging from its shape, is Mill Hill Hamburg; 3 is much like Dutch Hamburg, but richer in flavour than we usually find it. How can anyone expect us to name Grapes from three miserable berries? A bunch and leaves of each variety should be sent.

NAMES OF PLANTS (H. Ventnor).—*Ruscus racemosus*. (H. S. R.).—We cannot name from leaves only.

POULTRY, BEE, AND PIGEON CHRONICLE.

1876.

THERE is always the fear when undertaking an annual task for the twentieth time that the sayings and opinions of previous years will repeat themselves, and that the whole will become "tedious as a thrice-told tale." But our task is a kindly one, and the kindlier feelings of our nature never grow old, in the ordinary sense of the word. They, like generous wine, mellow and become better as time steals on. This is especially the case when we have to review the past, and to address those who, we believe, share our feelings, and with common gratitude praise the Goodness that has spared us to exchange our kindly greetings once more.

A review of the past is of necessity full of anticipations of the future. All believe none of the trials and shortcomings of 1876 will repeat themselves in 1877. Experience should enable us to avoid the rocks on which we split, and should be a constant beacon warning us when we approach danger.

It appears to us that poultry has a twofold mission to fulfil. First, it has to help to produce food, next it is calculated to afford a harmless, beautiful, and pleasing recreation. We believe these purposes have not been fulfilled, the quantity of poultry has not increased, and shams have in too many instances been very losing speculations. We will endeavor to trace these facts to their origin, and to point out a remedy.

It is an established fact that the supply of choice poultry does not increase; that during the scarce time of year, April, May, and June, it seems to diminish. It cannot be from lack of encouragement in the way of price. Thousands of fowls were last year sold at 7s. 6d. and 8s. each. A man many years ago made a bet that six hens should in a year pay better than six ewes. He won easily. Two things are needed—first, to have the best breed, next to produce the chickens at the most profitable time. It was hardly necessary to seek the best breed; that was and is known. Practical tuition was required, and that has often been given in our pages. We might take a leaf out of the book of our first great agricultural writers. They sought to produce at once the most economical and the most profitable animals whether for food or milk. They persevered, and they succeeded not by seeking all sorts of strange breeds and animals, but by improving those they had. This was done so judiciously that the qualities

have become hereditary, and with a guaranteed pedigree certain qualities may be depended upon.

It is in this sense shows are useful. They make comparison easy, and they afford an open book in which anyone may read; they are always well attended, and consequently profitable. They attract the eye, they have in view for it is known to those who attend to do with them that some breeds cannot be kept lean, and are obliged to be reduced at certain periods of their lives.

Our poultry shows have differed, inasmuch as many have not during the year been successful. With a very few exceptions they have shown a falling-off, and have ended in a loss. Committees and exhibitors do not understand each other. The first bow to dictation in the matter of publishing judges' names before the show; the other fancy the show cannot go on without them, when in fact their birds are valueless and useless without shows. They forget unless they attract the public their birds might as well stay at home. This is true of the largest as well as the smallest shows, and independent exhibitors are in consequence canvassed and solicited to exhibit. The shows are too numerous by half, and the best class of exhibitors have ceased to show, hence the widespread discouragement. The declension has been gradual but incessant since new rules and practices sprung up. Admission while the judges sit at work, surrounded by people with open catalogues in their hands, the knowledge that any good cheap bird will be snapped up by those who attend for that purpose—these things do mischief that no number of selling classes will remedy. The straining after a large number of entries, and the accomplishment of the fact by showing only single birds, causing a weariness of sight and body at the monotonous class of fifty hens, each occupying a single pen, and all so much alike that an unpractised eye can see no difference in them.

Those who eschew the shadow of exhibiting, and seek the substance in the shape of table poultry, dream only of very large establishments of thousands of hens, rows of buildings and poultry farms. There is always an idea that the supervision necessary in a small place may be avoided in a larger. This is a mistake, success in poultry as in anything else is the result of labour and painstaking. We hear much of eking out a small income by its means, but we are sorry to say such "eking" means to put more work on a maid who has already more than she can do. Nine out of ten of the failures of those who have tried poultry only to be deceived, arise from the fact that pride is too powerful with the ladies who wish to adopt poultry as a means of income. They would exact from the buyer as much defence as from a seller. It cannot be. Just as Solomon said, "the borrower is servant to the lender," so the seller must give way to the buyer. There is not the semblance of anything but "kindliness" in this, but we must tell the truth. As usual she is at the bottom of the well, but we will guarantee when she is found she will say there is help to be had from poultry. There will always be a difference between buying and selling. But it is not so much as people fancy. A man who wants to buy will buy where he gets the best quality at the lowest price without asking the social standing of the seller.

There must be a limit to everything, and if Dorkings were had larger than they were some years ago they would rival Geese. They maintain their full weight, nor do we think they decrease in numbers. There were formerly but two classes for each breed, now there are six—adult and young cocks, hens and pullets, selling classes of cocks and hens. The same may be said of almost all the classes. Cochins are stationary, if not inferior. Brahmas increase in numbers but not in quality. In these two breeds the competition decreases for the reason that prizes are awarded to hideous vulture hooked birds. People know not what to breed or what to show. Spanish have remained stationary, but they esquin come to the fore. Game as usual hold their own, and always will; as a rule at all our large shows they are the best judged of any of our classes. The cross of the Malay is visible in many of the birds shown, but the judges avoid it. The Malay as on the increase in numbers, there are no wanting excellent specimens among them, but there are also many birds that are not pure-bred—for instance, many are shown with an ample dewlap. We do not know to what to attribute it, but among the Hamburgs, favourites with everyone, in both breeds the Golden are much better than the Silvers. Some of the Golden-pencilled have been almost everywhere perfect. The Silver-spangled are better than the Silver-pencilled.

The French breeds, if by that name we mean the Crève-Cœur and the Honan, show excellent birds, but they have yet to prove they bring us any quality we did not already possess. The La Pêche show poorly.

The Polish increase in numbers and maintain their quality; they are glad of it. They are old and worthy favourites. Bantams are always popular. Sbrights make another class year after year. The Game increase in numbers and are good in quality. We still mourn the Cochins. In these as in their larger brethren, the various class gives any meritorious breed the opportunity of distinguishing itself. These seem to be the anti-currents from

which birds pass either to be returned to their varied companionship or to form classes. An attempt was made by the Lehigh to claim a class, and their claim was admitted. They contrived to send three pens to compete for two prizes. We suppose they should be sent back again. Turkey's appear stationary, but they for some time took giant's strides, and cannot always do so. The pure American seems to be disappearing from our birds.

Geese are as heavy but not as numerous as ever. The Rouen Ducks have beaten Aylesburys in every way, weight and numbers. The Labrador or Buenos Ayres Duck deserves every mention of praise for symmetry, brilliancy of colour, and diminutive size. The class for fancy Ducks has been a great and a deserved success. Birds that a few years ago were kept out of sight and only looked at by stealth, now bear the scrutiny of hundreds without blinking, and care nothing for it. They are also shown in exquisite condition. Carolinas and Mandarins are become common. They make room for Casaraks, Whistling Ducks, Bar-headed Geese, Chilean Pintail, and many others.

Our task draws to a close. It has not been a satisfactory one, but we have laid our duty to speak plainly to our friends and readers. Committees will find it difficult to please the business and pleasure element at the same time. The latter will come when it please, the former must come; "Tis its vocation, H.L." There is no reason why they should be antagonistic. Every pursuit under the sun ebbs and flows, and as a rule it is at the ebb it is most inclined to learn.

We always defer speaking of ourselves till the end. It is the least pleasing of all our duties. There is no reason why it should be so. We can lay our hands upon our waistcoats and say we try to do right and to fill worthily the places our friends have given us. That which has been given us we will do our best to keep. We never have nor will we cause any deserving man to be anyone. We will be parties to no man's ruin, and we will be openly published on our page. We will, to the best of our ability, deal kindly and seek the merited esteem of all with whom we have to do. We have prospered during the past year, and with full hearts we wish, in this our first number of 1877, to subscribers, contributors, and all our friends—

A HAPPY NEW YEAR.

PREPARING FOWLS FOR EXHIBITION

When we exhibited fowls, which we did at one time quite largely, our birds intended for exhibition were taken in hand some two weeks previous, and kept in a room or pen well littered with straw or hay, under which was spread sufficient earth to soak up all moisture which might be dropped. The morning feed was always cooked meal and bran, and about a table-spoonful of linned oil-cake to each fowl. At noon it was cooked meat and chopped onions, cabbage or other vegetables. At night, raw meat and whole grain, either corn, wheat or barley. Gravel and lime rubbish was always within their reach, also fresh water with a little tincture of iron or tonic of some kind added. Twice a week we gave each bird a bit of assafœtida the size of a hazel nut; this increases the appetite, as well as acting as a corrective and preventive of disease.

Birds thus fed will acquire a hardness and lustre of plumage which is foreign to those picked up at random from among the flock.—(American Pet Stock Bulletin.)

BROUGHTY FERRY SHOW OF POULTRY, &c.

This was held in the Good Templar Hall, Broughty Ferry, on the 22nd and 23rd ult. The following is the list of awards:—

- POULTRY.—Dorkings—Cock—1 and Cup, G. S. Robb. 2, R. Craig. 3, Mrs. Armstrong. 4, J. Macdonald. Cuck—1 and Cup, G. S. Robb. 2, Mrs. Armstrong. 3, Mrs. Davidson. 4, Mrs. Davidson. 5, J. M. Beth. W. W. Webster. 6, J. M. Beth. 7, J. M. Beth. 8, J. M. Beth. 9, J. M. Beth. 10, J. M. Beth. 11, J. M. Beth. 12, J. M. Beth. 13, J. M. Beth. 14, J. M. Beth. 15, J. M. Beth. 16, J. M. Beth. 17, J. M. Beth. 18, J. M. Beth. 19, J. M. Beth. 20, J. M. Beth. 21, J. M. Beth. 22, J. M. Beth. 23, J. M. Beth. 24, J. M. Beth. 25, J. M. Beth. 26, J. M. Beth. 27, J. M. Beth. 28, J. M. Beth. 29, J. M. Beth. 30, J. M. Beth. 31, J. M. Beth. 32, J. M. Beth. 33, J. M. Beth. 34, J. M. Beth. 35, J. M. Beth. 36, J. M. Beth. 37, J. M. Beth. 38, J. M. Beth. 39, J. M. Beth. 40, J. M. Beth. 41, J. M. Beth. 42, J. M. Beth. 43, J. M. Beth. 44, J. M. Beth. 45, J. M. Beth. 46, J. M. Beth. 47, J. M. Beth. 48, J. M. Beth. 49, J. M. Beth. 50, J. M. Beth. 51, J. M. Beth. 52, J. M. Beth. 53, J. M. Beth. 54, J. M. Beth. 55, J. M. Beth. 56, J. M. Beth. 57, J. M. Beth. 58, J. M. Beth. 59, J. M. Beth. 60, J. M. Beth. 61, J. M. Beth. 62, J. M. Beth. 63, J. M. Beth. 64, J. M. Beth. 65, J. M. JUDGES.—Poultry: Mr. M. Leno. Pigeons: Mr. A. Frazer.

RIPON SHOW OF POULTRY, &c.

The second winter Show was held at Ripon on the 27th and 28th ult., when entries were far a-head of those of last year. Unfortunately the hall in which the Show was held was not large enough, and several rooms had to be brought into use, the lower one where the poultry were placed being very dark, and candles were requisite for the inspection of the birds.

Turkeys and aquatic fowls headed the list with some good classes, the special prizes going to a grand pair of Turkeys. *Dorkings* good, and *Brachmas* a fair lot and well placed; the *Cochins*, however, fairly leading this section with a grand pen of Buffs. *Spanish* not a large class, but the winners good. *Hamburghs* were heavy classes, the special prize being awarded to Gold-spangles. *Game* had three classes. In Reds a substantial pen of Brown Reds were placed first; the second being Black Reds, both old pens. Any other than Red were first Piles and second Duckwings, the first in splendid style, the last superb in colour; but we preferred pen 164 (Nelson), Duckwings, which might have been placed without fear of contradiction. Single cocks, first and special a Brown Red cockerel, grand in colour and with the most perfect breast, but as yet he does not know how to behave in a show pen, showing some timidity. *Game Bantams*, any other, were decidedly rusty; but some allowances may be made on account of the light; second (Nelson) by far the best. Single cocks, first a grand fellow, a true Black Red; the second, a Brown Red, we thought a little large, but stylish withal. Bantams, any other, were first Silver Sebrights, second and third Blacks. In *French* the winners were Crèves. In *Polish* the winners were Silvers; but the second had a very bad shaped crest, although the hen was a good one. The point cup for poultry was won by Mr. Belton.

Pigeons being single birds were a good entry, and some grand birds put in appearance; but, as will be seen, we did not think them well handled in judgment. Carriers a good class and well placed, the first and special being given to the first Black, which is a grand bird in all particulars; second, also very good. Pouters were good; first a Black cock in grand order, closely run by a Blue cock, the best blown bird in the class; pen 294 (Beckwith), a Red, was also a grand one. Barbis, any colour, was a decided mistake, first being a poor Black cock with small head and sickly eye; the second was rightly placed and a good bird, but perhaps a little more pinched than we have seen him shown. Pen 304, the best Black hen in the fancy, was passed without a commended, and should have been placed first without a second look. Tumblers, Short-faced Almonds, were quite as bad; first was a cock that has seen better days, and should not have marked here, being a deep mahogany ground colour, and quite black on breast, throat, and neck hackle; pens 312 and 313, which, if we mistake not, won the cup and second at Birmingham, and also winners at the Palace, but only second here, should have been an easy first and second; pen 312, highly commended, was by far the best. Both birds are a beautiful almond ground and thoroughly spangled, and very good in head, beak, and eye properties. Tumblers, Short, any other, were good and well placed; first an Agate, second Red, and third a Kite. In Tumblers, Long-faced, the best bird in the class was left out—viz., a Black Bald hen, first and medal at Newcastle, and first at Leeds, this being a most brilliant-coloured bird, very small, and a true Long-face; pen 334 (Thresh) first was a good Black Bald, but not equal to the above; second a Yellow Mottle, very pale in colour; third a Rosewing, a good bird.

In English Owls first was a bird of very waxy colour, straight and spiky in beak, with a little skull over the eye. The best, and which stood clear of all others, was the extra second-prize bird, a bird which the same Judge has often placed first in several competitions; pen 362 was a grand young bird and placed third. In foreign Owls we preferred pen 364 (Alderson) to all others as small and most correct in skull; the second was rightly placed; the first bird was both flat-skulled and large. These were all Whites, but a grand little Blue was shown by Mr. Baker. Turbits, 374 (Alderson) a Blue, was a head of all others, such quality of spike, mane, and gullet is rarely seen, and this we should have placed first; the first a good Bloo, was well worth a third position. Pen 381 (Seaton) ought to have been second; this is a Yellow, small and grand in every particular. Pen 382 also a Yellow, and quite to our taste. Nuns well placed, as also the Magpies. The rest of the classes were good, and the awards were generally well placed. The point prize was won by Mr. Baker.

Rabbits had but two classes, and several pens were empty. In *Lop* first was a Fawn-and-white doe; second Sooty Fawn, 22 by 2; third Black-and-white doe, 22 by 2. The latter is

quite worn out for the present, and needs a long rest. In the next class a Gray Dutch faulty only in size was first, second a Silver-Grey, and third a Silver-Cream.

Cage Birds were a good entry, and, as before stated, were judged by candle-light; but when the light became better we saw no cause to alter any decision. Belgians had but three entries, but these were good; the first also taking the special for the best bird in the Show, it being without exception the best we have seen for some years, the distintest head attached by a long neck to a superb pair of shoulders, which were carried in grand style, the body and tail long and straight, and in the finest possible order. Yellow Norwich good, the first a grand sound-coloured bird, second losing in little. In Buffs, also, the class was good. The Marked classes were two of the best we have seen for some time, a very slight muddiness on the flue or fluff only deciding between the winners and losers. The whole of the winners in both classes were four-pointed birds, the same remarks applying also to the York-hire-marked birds. In Crested Norwich were a few good birds, but the selling class, and these were really grand in both classes, ground spangling, esp. and size alike good, the first-prize Silvers running very hard for the special. In Mules first was a Clear Buff, and second a four-pointed Yellow. In the Variety class first was a Jonque Cinnamon, second Coppy, and very highly commended a Cinnamon. The Local was a good class; the first, a Belgian, was well equal to a second position in its own class; second a Scotch Fancy, and third a Coppy. English birds were a splendid class; first a Goldfinch, second a Finch, third a Linnet. In Parrots were some grand King Parrots; a good Grey was, however, placed second. The Selling class was a good one.

flourish as well some distance from a loft containing a large flock at liberty as near it—provided the soil is as good. I have also known a plant in a flower garden to be much injured by them, owing to its possessing such tender and succulent leaves, when all the many plants around were untouched. A head of lettuce occasionally given is recommended for birds that cannot get young beet tops in a neighbouring garden; and fanciers sow rape or other seed for them, that they may peck at the young plants as the latter stand in the earth. I should think it would be a good plan to plant the seeds of some tender vegetable in boxes, at such times that the plants may attain the height of several inches, at different periods through the winter. These may be placed in the loft in the succession in which they were planted, say at intervals of a week or two. This would be somewhat laborious. In the summer I find the common purslane or "pusey," answers excellently for a salad. It is abundant, and eaten with a relish by the Pigeons. I reserved a small corner of the garden for its growth, and now and then threw a bunch or two into the loft where my Pigeons were confined. The stems are about all they leave untouched. It is a troublesome weed; but cherish a few roots of "pusey" for your cooped-up Pigeons. Don't allow it to go to seed, unless it is scarce in your neighbourhood.

[Commenting upon the above extract from the *American Fanciers' Journal*, I would say that only in summer Pigeons need or seek any green food. In winter or in cold chilly weather it would do them harm. I have found that Tomblers chiefly care for green food. In the summer I have had them walk through rows of Potatoes, picking at the weeds and returning to the loft with their beaks quite green. Jacobsins, the variety I now keep, never seem to seek it. One condiment or helper of digestion all Pigeons want, and seek for greedily—viz., gravel. I have a large space of gravel, and they are frequently pecking it, especially new comers. I would say that salt, broken up old mortar, and gravel are requisites to health; but green food is an open question, and I am not sure it does the birds any good, but rather harm, as I have noticed it produces purging.—WILTSHIRE RECTOR.]

THE annual Show of Pigeons by the National Peristeric Society is to be on the 9th and 10th of January at the Crystal Palace.

TO PRESERVE EGGS.

I HAVE experimented with many nests of eggs this year, and find that butter or grease of any kind with me will certainly keep the eggs clear, but incubation will not begin. I have tried a solution composed of glycerine and olive oil with the same result. If you wish to keep eggs fresh for six months, take 4 ozs. of the best glycerine and 2 ozs. of the best olive oil, shake well up together and rub on the eggs. I had some eggs for breakfast that were put down last January in a cool cellar that were treated with a coat of this egg-preserved, and packed the large ends down in fine sand or salt, and you could not tell them from freshly-laid eggs. Out of twenty-four dozen that we have used this month that were put down in that way in January and February, five only were bad, and they only had a strong musty smell.—DR. W. C. MUNROE (in *American Fanciers' Journal*).

DO BEES MAKE HONEY?

In the *Rural New-Yorker*, Mr. A. Wilson of Onondaga, New York, asks this question, and then answers in the following words:—"I do not know why there should be any mystery about this question of bees making or gathering honey, to me it is as clear as sunshine. Suppose we take the best sugar, and make a gallon of molasses or syrup, and put it where the bees can get it, and they take it into their hives, and in time cap it over in the cell; but, in the meantime, let us keep a little syrup for comparison. After a while take an extractor and remove the syrup from the comb, and it will be found to be honey, and quite different from the reserved material; in fact, the one is honey and the other is not. The bees, of course, did not make the honey, but changed the flavour only. It will not be clover honey, linden, or buckwheat honey, but syrup honey. Their Creator has given the bees the power of changing the flavour of the sweets gathered, and it is then called by us honey. We may say that bees made it, and so we may say that cloth made of wool is woollen; and of flax, linen; of cotton, cotton-cloth; and so with honey. Bees cannot make buckwheat honey into clover honey, any more than we can make cotton-cloth out of wool."

In the above quotation Mr. Wilson's ideas appear to me to be pretty accurate and intelligible. His advice, to keep a little of the crude syrup to compare with that which is refined by the bees, is very good indeed. May I ask the readers of this Journal who have any doubts on the question to take his advice, and test the matter for themselves? The experiment will be found both

simple and satisfactory. In a summer day any unprejudiced person may settle the question to his own satisfaction in a few minutes by extracting both crude and perfect honey from a hive at the same time, and comparing them. It will be found that the honey which has been re-swallowed and stored-up has both body and flavour, in every sense different and superior to the crude honey as it is carried from flowers and disgorged in the centre combs of hives. Mr. Wilson says syrup made of sugar and water becomes syrup-honey. Though the bees thicken and sweeten the syrup, and greatly improve the flavour, I do not call it honey. It is, after all, only syrup refined and improved by bees, and is more the smell and appearance of all kinds of genuine honey. To sell syrup honey in any form as genuine flower honey would be a fraud and imposition. For many years past I have denounced this practice as dishonest, and raised my voice against it.

The American writer is quite right in his remarks about the distinct difference of this and that kind of honey gathered from this and that kind of plant. Last week a Welsh lady sent me a small bottle of honey which she obtained at Arundel in Sussex, on making a visit there last autumn. She did not like it, but wanted my opinion of it, and to know the kind of plant that yielded it. This Arundel honey pleased me much, as it was exceedingly clear and highly scented, and with a rich aromatic flavour. I never tasted better honey, and fancy it was gathered from wild thyme.

As the question of crude and perfect honey has been often before the readers of this Journal I need not dwell longer on it here. Young apiarists will find the subject a very interesting one, and if they could only be induced to put the question to the test of a simple experiment, they would find that bees not only gather honey, but refine and remodel it after it is gathered. In this remodelling process there is much water eliminated. This water escapes as vapour generally by the pores of hives, and during the nights much of it may be condensed and caught as it escapes.—A. PETTIGREW.

BEE PASTURE.

A CORRESPONDENT "P. B. P." has asked for a short description of places and flowers from which large harvests of honey have been obtained. It is no easy matter to convey in words what is and what is not a good district for bees. Though some districts are much better than others for honey-gathering, success is often attained in apparently unfavourable places. Fruit trees and pasture fields (for cattle) are properly considered the best provisions for bees in Great Britain. Orchards and dairy-farms are the principal features in the landscape from a bee-keeper's standpoint. All other things being equal, the south and warmer counties are better than the northern districts. The south is better than the north in more senses than one. Bees in the south begin breeding earlier, and as the climate is warmer the flowers yield greater supplies of honey; for climate favourable for honey-gathering in this country can never equal France, Italy, and America.

With a view to assist "P. B. P." and others in forming a pretty correct notion as to the best places and pasturage for bees, I will here name some of the most common and best kinds of plants for honey which grow in Great Britain. There are about one hundred kinds of plants grown in this country which yield food for bees; in this letter about twenty only will be mentioned.

In early spring the flowers of crocuses and some kinds of willows (*Salix*) are very tempting to bees; border hyacinths, single wallflowers, and an early tussock are haunted for their sweets. But the real honey season begins when the fruit trees come into blossom. The flowers of all our fruit trees yield large supplies of excellent honey. I may safely say super-excellent. Gooseberry, plum, currant, cherry, peach, apricot, pear, apple, raspberry, and black or bramble berry, are all honey-yielding plants, and are well known everywhere.

Field mustard (*Sinapis arvensis*) a mere yellow weed in corn fields, is a most valuable plant to bee-keepers in some districts, for it continues a long time in flower and yields great stores to bees. The honey from this plant soon candies, and the combs built from it are tinted yellow. The flowers of turnip, cabbage, and all the brassica tribe are of the same cruciferous shape, and yield honey in abundance. They are seldom allowed to flower in this country.

The field bean is another valuable plant for bees, and it continues a long time in flower, and is extensively cultivated. The flowers of this plant have to be tapped near their bottoms in order to obtain their honey. The flowers are so deep (like those of the red clover) that bees cannot reach the honey in their receptacles from the top, hence the flowers are pierced below, and much rich treasure is extracted from them.

Sycamore (or plane) trees are valuable to the bee-farmer, as they come into flower before the apple blossoms are over and continue till white clover comes in. In this country the honey lies on sycamore flowers and is clammy to the touch; from

sycamores bees gather honey very fast; it is of a greenish hue, very rich and highly flavoured. This green honey from sycamore and gooseberry trees is preferred by my palate before all other kinds of honey.

White clover, the queen of all honey plants, comes next in season. It lasts from the beginning of June till the end of July. In the year 1843 bees in Middlesex gained weight till the end of September, chiefly I believe from white clover. The honey obtained from this plant is clear and transparent to the eye, and imparts to the palate a rich, pleasing, smart smack which everybody likes. Some farmers in laying down grass land use more white clover seed than others, and wherever lime and bone dust are used as manure white clover is most abundant. It is incomparably the best plant for bees in Great Britain, and is found in every county.

Lime trees flower in July for a short time and yield honey freely. The American bee keepers, both in Canada and the States, have a great deal to say about basswood or the Linden tree as a honey-producer. I fancy it is a kind of lime tree, coming into flower late in the season and lasting a long time. Some bee-keepers speak of making plantations of basswood for bees alone. The climate of Great Britain is not so trustworthy as certain as that of America and some parts of southern Europe. If mignonette grows as well in those favourable climates as it does in our country I fancy it would be the best and most profitable plant to cultivate for bees. I have no hesitation in saying that an acre of mignonette would yield 20 lbs. of honey every fine day in this country—what would it not do in warmer countries?—it continues three months in flower, and grows almost in any kind of soil.

Heather, wild heather, the last in flower but not the last in importance and value of our honey plants, comes into flower in August and lasts about three weeks only. In this year (1876) my bees failed on the heathery hills of Derbyshire, but for ten years previously they stored up large supplies of it, and during some of those years they failed on the clover. It is hardly possible to convey a correct idea to the unstructed bee-keeper as to the great work done by bees on the moors in a short time. The moorland honey is high-coloured, and stronger in flavour than any other English honey. The Scotch people like it, but generally speaking it does not suit the English palate so well; but even in Glasgow fifty years ago flower honey was sold at a higher price than heather honey.

Having lived in several counties I may here give my opinions of them from an apianian standpoint. My native county (Lanark) is comparatively cold and bleak with a heavy clayey soil. On the Clyde, which runs through its centre, there are some large and fruitful orchards, which greatly help the bees in several parishes of the county. The fruit-tree blossoms are followed by field mustard, white clover, and heather. The bees there do well. Ayrshire is probably a richer county for bees than Lanark. I have not lived elsewhere in Scotland, but fancy that the rich loam of mid and east Lothian are rather too much devoted to the production of grain crops for bees to do well there.

Around London for many miles grass land prevails. Fruit and forest trees and white clover are what the bees work on there. Some five and thirty years ago I lived near Barnet, and found bees to do exceedingly well. I formed a favourable opinion of the whole district between London and St. Albans. I have not seen much of Kent, but from all I have heard of it I should say it is a good place for bees. Lancashire, in which I have spent twenty years of my time, taken as a whole is one of the worst counties in England for bees. On the bank of the Mersey between Manchester and Liverpool they do pretty well.

Cheshire, as a whole, is a good and eligible place for bee culture, presenting a fair pasture of varied kinds. Around some of the larger towns, such as Chester, Knutsford, and Altrincham, we find much fine pasture land and forest trees. On the large dairy and cheese-producing farms bees will not fail to do well. Sely being on the north corner of the county and butting against the river Mersey, and near Manchester, is chiefly used for market-garden purposes, and is therefore deficient in white clover. Cheshire is perhaps as good a county for bees as any other in the north of England. About Buxton in Derbyshire, which is so high and bleak that corn does not grow well, bees gather great stores of honey. The calcareous soil of the Buxton district yields plenty of white clover, and heather abounds within easy distance of the place.

In the East Riding of Yorkshire bees do very well—wedging their hives full of honey on every favourable season, and this without much care or attention.

In closing this letter let me refer to a question often put as to a district or pasture being overstocked with bees. "Is it possible to overstock a parish?" Yes, though I have never seen one overstocked. I believe it is often done in America by apianians who keep hundreds of hives. It is but reasonable to believe that the bees of fifty hives will do better than the bees of one hundred hives on a given pasture. But all bee-farmers may add farm to farm by spreading their hives over a wider area,

and this may be done without having to pay a heavy rental.—A. PETTICREW.

OUR LETTER BOX.

LIME FOR FOWLS (W. H. W.).—Quicklime and sand siftings from a brick-layer's yard would not be injurious to fowls. Give your moping cocker some bread soaked in lime.

DARK BRAHMA HEN (A Victim).—Your only remedy is to let her in the County Court.

JERSEY POULTRY SHOW (Exhibitor).—We received the prize list just as we were going to press.

FOWLS FOR WINTER LAYING (Mrs. W.).—Early-hatched pullets of almost any breed will, if properly fed, lay during the winter months, and as you possess both Dorchings and Brahmas you have no need to seek for other breeds for the purpose required.

PURCHASING BEES (Suzette).—The best time to purchase bees of breed in autumn or winter, for then they may be removed without risk of breaking combs or suffocating bees. In winter, too, bees do not go far from home, and may be easily removed from a garden at no great distance of, say a mile, without danger of the bees returning to it. We advise to begin with two stocks, and purchase them of a cottager in your own neighbourhood, for if a commencement be made with only one hive and something goes wrong with it much discouragement may be felt. The "Handy Book of Bees" is one of the best for beginners; in it you will find all the information you are seeking.

METEOROLOGICAL OBSERVATIONS.

REMARKS.

- 27th.—Raining all day, at times snow or sleet; wind high and very cold.
 - 28th.—Early morning and afternoon; windy but starts night.
 - 29th.—Wet in early morning, fair forenoon; rain in afternoon and evening; fair but windy at night.
 - 30th.—A beautiful day throughout; warm, dry, and bright.
 - 31st.—Windy and showery all day; at times very bright, but only for a short time.
 - 1st.—Very wet all the forenoon; at times after very bright, and at times very heavy rains.
 - 2nd.—A very pleasant fine day throughout; rain in evening and night.
- Another wet week, and a very warm one, the temperature being nearly 12° higher than the previous one.—G. J. SYMONS.

COVENT GARDEN MARKET.—JANUARY 3.

Our market has been so quiet since Christmas that we have no alteration to quote.

From observations taken near London during forty-three years, the average day temperature of the week is 41.1; and its night temperature 29.5.

HORTICULTURE IN 1876—A RETROSPECT.

HORTICULTURE (in which term I would comprehend all the various departments of gardening) has, like everything here, its varied scenes of prosperity and adversity, and on looking back over another year we have to chronicle gains and losses. In giving, then, my view of matters connected with it during 1876 I do so only from my own standpoint; by no means claiming for myself any right to do so, but at the same time believing that I have had some facilities for forming an opinion. It is known to the readers of "our Journal" that I have every year opportunities not only of seeing what is doing in the metropolis, but also in various parts of the country, and during that now closing have visited the west and north of England, and crossed the border into Scotland; and as I have recorded the results of these visits from time to time, I have no intention of doing more now than making a few general observations connected with them.

I think it is very clear that if amongst the arts of peace there is one at any rate that increasingly finds favour with all classes in our favoured land more than another it is gardening; and that if our neighbours on the Continent twit us with the low character of our schools of painting and sculpture, with our poverty in music and want of taste in architecture, we may fairly take our stand on our gardening powers and defy the world. And this love for our gardens has suffered no diminution in the past year. Whether one visits the stately grandeur of Chatsworth, Drumlanrig, or Trentham, the wind-swept garden of my friend Mr. Mackenzie at Newton Stewart, or the densely smoke-pestered garden of good Ben Simonite at Sheffield, it is ever the same. Where princely fortunes and grand facilities combine there is such a completeness that one wonders what can be the meaning of alterations and additions, or what there is to alter or add to; while to surmount obstacles and overcome difficulties is the task that loving hearts and hands desire to accomplish and bend their energies to effect, and I know not if real gardening power is not displayed in the latter rather than in the former case. Through all classes and in all ways this love holds good. Enterprising purveyors for novelties send their collectors all over the world to rife nature of its treasures, and give them to us for our gardens; while hard-working men at home strive to increase our pleasures by producing new varieties of flowers, fruits, and vegetables; and if at times they give us novelties which are only so in name, and improvements which are improvements at the wrong end—why, we must not set them down as dishonest; they have looked at these things with a parent's fondness, and have been unable to see the defects which strangers do, and we must pardon what we suffer in such cases for the good they have done us in others.

In looking back on the past year I do not call to mind at present anything very remarkable that will make this

year notable in novelties; while of such as have come under my own special observation I shall hope to say something when I send forward my annual "notes from my garden." While, however, admitting all this, I think it becomes a question whether flower shows are increasing in favour. The past year has been such a one with regard to metropolitan exhibitions as will probably never be seen again; they came so rapidly one after the other that exhibitors must have been at their wit's end. The Royal Botanic Society will no doubt hold its usual exhibitions; and as to the Royal Horticultural Society, I think we may conclude that its days of grand flower shows will be fewer, even should Mr. Wilson's plan for its resuscitation be successful. The opening of the Aquarium at Westminster, and the placing of the floral department under the care of Mr. J. Willis, gave an opportunity for the inauguration of a series of shows which for munificence in the amount of prizes we can never expect to see equalled. The attempt to break through the ordinary arrangement of flower shows was not very successful, but better or more extensive collections of plants and flowers have hardly been brought together before. But this is all a thing of the past. The Alexandra Palace, which has vied with its sister at Sydenham in the matter of flower shows, is shut up, after the testimony of all concerned that they did not pay. The Crystal Palace authorities say the same, and have in consequence cut-down their schedules of prizes. While in the provinces there seems to be an increasing tendency to try and attract people by other things; and horse shows, dog, cat, and poultry shows, fireworks, and amusements of various kinds have been added to the more legitimate charms of music. This is not a healthy sign, and either indicates want of taste or that there is so much sameness year after year that people tire of shows. There are, it is true, some notable examples to the contrary, but that this is the general state of things is, I fear, too true. There also seems to be an increasing unwillingness on the part of owners of large gardens to go in for exhibiting, and were it not for the exertions of professional horticulturists even our metropolitan shows would be meagre indeed.

I have been twitted for saying that I believe florists' flowers are at a discount in the south, and while I cheerfully acknowledge the attempts that are being made to revive an interest in them, I am compelled to abide by my view. I have been accused of disloyalty to the cause for having said so. To all who know the deep and hearty interest I have taken in florists' flowers all my life this will seem simply an absurdity. No! I am no more disloyal to them than the "Iron Duke" was disloyal to his country when he stated, some years before the Crimean war, that our field artillery was the worst in Europe; for it led to that thorough reorganisation of that important branch of our service which has made it what it is, and no cause is served by being blind to its defects. There is one flower the votaries of which seem every year to increase, and it is more especially a southern flower, and that is the queen of them all—"the Rose." Not an exhibition of it is held but numbers of amateurs crowd forward to

contest the palm. It alone of all flowers can support a distinct show for itself; and Maidstone, Hereford, Exeter, Chipping Norton, Helensburgh, Newton Stewart, Birmingham, &c., besides the Rose shows of the Crystal Palace, Alexandra Palace, and Aquarium, are undeniable proofs how popular, and increasingly popular, the Rose is; and the closing month of the year has witnessed the auspicious beginning of a National Rose Society, which it is hoped may foster and still further increase this widespread interest.

And while speaking of gains and losses we must not omit those personal losses which horticulture, like all other things, has to count up as the years roll by. All who know kind and genial John Pearson of Chilwell will feel that he has left a blank behind him not easily in his way filled up, and the growers of Pelargoniums and Grapes will long cherish his memory for the pleasure he has afforded them. Less conspicuous, but equally loved by a large circle of his acquaintances, William Cutbush of Barnet has passed away; his business having been taken up by his hearty and widely-respected brother, James Cutbush of Highgate. The florists, too, have to lament the loss of two well-known men in their day and generation—Richard Heady of Stapleford, a most successful grower and raiser, whose name will ever be regarded by all who love the Auricula, Tulip, Carnation, and Picotee. Heady's George Lightbody, Alderman Wisby, Petronella, Sarah Heady, King James, Chancellor, &c., all testify of his success. Practically he had been dead to the horticultural world for some years. Nathaniel Norman of Woolwich, too, is a name which Picotee and Pink growers cherish. He was the raiser of Mrs. Norman, Favourite, Lord Nelson, Mrs. Williams, and other Picotees; and of Charles Williams and other Pinks. Lastly, all have also lost, not through death but ill-health, as a grower and exhibitor, that most successful cultivator of the *Ranunculus* Mr. Carey Tyeo of Wallingford. On the side of gains we may record the re-appearance in the arena after an absence of sixteen years a most energetic and successful florist, Mr. E. S. Dodwell, well known in former years for his success as a grower of Carnations and Picotees.

Such is my retrospect. I confess the outlook does not seem to me very hopeful, but unexpected things may turn up, and at any rate all good gardeners know they cannot always have sunshine.—D., Deal.

POTATO CULTURE.

THE notes under this heading on pages 463 and 510, vol. xxxi., brief as they are, ought not to be let pass unnoticed, because the arguments of the writers are unsound and their deductions false and opposed to the teachings of experience.

The fallacy of the early-planting system has long been exploded, and the fact established that frost-bitten haulm is never so robust in its subsequent growth as that which has sustained no check. What happens when the haulm is cut-down to the ground by frost? Precisely the same thing as when we nip-off the leading shoot of any other plant—a number of lateral side shoots of moderate strength spring up in place of the one vigorous shoot, inducing a crop of numerous under-sized tubers instead of a lesser number of large tubers. Apart from the great risk from frost which such untimely planting entails, the condition of the soil would in most years be unfavourable; and even if it were tolerably dry the evil effects of trampling upon it in midwinter, especially if at all of a close heavy texture, would be perceptible throughout the season.

It is just at this time of year that seed Potatoes so often sustain irremediable injury; and as this is one of the primary causes of failure, it may be well once more to describe briefly the most important points of what may not inaptly be termed common-sense Potato-culture. These points are four in number, and may be stated as—1, The management of the seed; 2, The time to plant; 3, The time to take up the crop; and 4, Storage. Taking them in this order we have

1, The management of the seed. It was once thought that seed Potatoes must be made green by exposure to light before they were stored for the winter. How or whence the idea arose that the tubers could derive any benefit from this process I am at a loss to comprehend, for it is quite certain that it is unnecessary either for the promotion of ripening or the keeping of the tubers, and I fail to see how else it could be thought to affect them. Throw Potatoes in a heap, and whether they are green or any other colour they will sprout; lay them out thinly and they will sprout—nothing can prevent it; but

then in the heap the sprouts growing long and weakly must be broken off, hence arises wasted tissue and weakly growth. Laying thinly upon the seed shelves with the air and light playing among them, the sprouts growing slowly are proportionately stout, are not broken off, but cherished with jealous care, and by the time they are planted are just so many small plants crested with miniature leaves, bristling with rootlets, and with such a reservoir of nutritious juices in the plump tubers that they spring to the surface as if by magic, growing with vigour and precision as though each plant were cast in a common mould. It was a good many years ago that I learned this lesson, but I suppose the feeling of astonishment and of pleasure with which was experienced when its full importance was grasped will never be forgotten. At that time I was, like "A YOUNG AMATEUR," an advocate and practitioner of early planting, doing all that lay in my power to get the seed in the soil in January. I had done so, and am afraid that I congratulated myself upon being ahead of my neighbours when I went into a certain garden two months afterwards and found that not a Potato had yet been planted. Fortunately for me I had to repeat my visit a little later on, and there were the Potatoes not only planted, but with their shoots growing strongly well above the surface, without a failure or break of any kind, offering a striking contrast to the ragged appearance and weakly growth of my miamansed beds. Before I left that garden I learnt more about Potato culture in one half-hour than I had done in all my previous experience, and ever since then I have applied to practice the lesson so fortunately learnt.

2, The time to plant. This should in all cases be ruled by the weather and condition of the soil. Very calmly and confidently can we now await a favourable time, a glance at our seed shelves showing us that our seed tubers selected and laid on end in single layers at the time of lifting are slowly yet most surely making such progress that of the two we would prefer planting at the end rather than the beginning of March, not much caring if we have to wait till April, for we know that once in the soil growth will be so strong, rapid, and certain as to lead to early maturity and an abundant crop, which we will not subject to the slightest injury by exposing any part of the growth to the influence of late frosts.

3, The time to take up the crop. This is undoubtedly the most important point of all, for upon it success or failure depends in ninety-nine cases out of a hundred. You may have the best soil, carefully prepared seed thoroughly well planted and cultivated, and yet a fine crop will be spoilt and all your labour lost by a single blunder in the lifting. I have repeatedly called attention to the importance of this matter in the pages of the Journal, and yet, to my very great regret, I find no general improvement taking place. Lift your crop the moment growth ceases, and you will save every tuber. Is not that plain teaching? Who is there so obtuse as to be unable to comprehend this? Do you wish to avoid the blight and preserve the entire crop? Well, you can do so; at any rate, I am able to do so year after year, and I possess no special advantages (rather the reverse), and therefore I fail to understand why everyone else cannot do the same. All that is necessary is simply to watch the growth of the haulm closely, and so soon as you are convinced that it has stopped you have nothing to do but to dig up the tubers and convey them to the storage without the loss of a single day. "What!" you will say; "dig up the Potatoes while the haulm is green and the tubers unripe?" Yes, I answer; that is precisely what I want to persuade you to do. I know it is a stumbling-block difficult to get over, because it is so different to the old easy-going method of letting the haulm decay and the crop remain in the soil till late in autumn; but I hope to convince you that it is worthy of adoption for every reason, and to this end I cannot do better than explain its beneficial effects as realised in my own practice. In doing so I can write with confidence, for I am telling no new thing, describing no novelty, advocating no rash or untried theory. Six years ago I urged upon the public the importance of early lifting, and subsequent experience has proved that I was right. In the year which has just passed away the main crop ceased its legitimate growth somewhat sooner than usual, so that I was able to begin lifting on the 10th of August, and to finish on the 15th. It was glorious weather, but intensely hot. The soil was so warm and dry that the tubers were literally thrown into the sacks "all hot." The crop was a fine and most abundant one, without a trace of blight or a blemish of any kind; so that while our neighbours are all complaining of the ravages of the blight (many of them

have lost quite two-thirds of a really fine crop), we revel in abundance of sound tubers. Why? Not because peculiar advantages of climate, soil, or cultural skill are found here, but simply because timely lifting is practised.

Never was there a more favourable season for the lifting than that of last year, and yet it was lost. The fine hot dry weather departed, the usual rainy season set in, second growth followed in the haulm, the tubers became changed into seed and put forth an abortive crop of other tubers, blight followed, and then arose the oncray at the severe but not unmerited loss. Why will not good people help themselves a little, and avoid an evil when it is in their power to do so? All that is wanted is a little care, energy, and forethought. Only resolve to save the crop if it is possible, and little difficulties will easily be overcome; and this brings me to my last point—sometimes made a difficulty of.

4. The storage. A short time ago when explaining the beneficial results of early lifting to a gentleman having the management of several large estates in the south of Ireland, I was asked, "How about the storage?" Starting from the admitted fact that most of our people are without storehouses or sheds of any kind, how can the Potatoes be stored so as to avoid injury from the excessive sweating or heating to which they would be liable when lifted in an immature condition?" I replied, that the storage might be a difficulty, but it was not insuperable, far from it. Given a field of Potatoes, a tree or two, and a bog covered with Heather, and it seemed to me that I had everything ready to my hands. In a corner of the field I would make a pit, taking care to surround it with an open drain to carry off water; from the trees I would cut poles to make a roof to be thatched with Heather brought from the bog, and I should have an excellent storehouse quite dry and impervious to frost. I quote this particular case as it is an extreme one, my object being to show that there is no difficulty in this respect which might not be overcome by adapting our plans to existing circumstances. Of course everybody would like to have a storehouse replete with shelves and every convenience, but the want of such desiderata ought not to hinder the practice of early lifting, nor can I suppose a case in which the method of culture once more set forth might not be followed. If such a case is supposed to exist I invite discussion in the pages of the Journal for the general good. Tell us your difficulties and let us see if we cannot find a remedy.—**EDWARD LOCKHURST.**

CHRYSANTHEMUMS FOR NON-EXHIBITORS.

There have lately appeared in the Journal some excellent articles on growing Chrysanthemums, chiefly addressed to those who wish to grow them for exhibition. There is, however, another and larger section of the community who would like to grow Chrysanthemums, but hesitate to do so on account of the expense incurred to grow them as they are grown for exhibition, and it is to those I wish to address these remarks.

Growers for exhibition recommend the cuttings to be put in November. Whether this is absolutely necessary I am not in a position to decide, as I have had no experience in the matter; but this much I can say, that for growing for home decoration November is quite four months too early to strike the cuttings, and if very large plants are not required the last week in May is not too late. This will give time for the plants to fill 8 to 10-inch pots, and with twice stopping (which must be performed as soon as there is anything to stop) they will make very fair specimens, requiring no training beyond four or five small stakes and a little matting or twine; and the large-flowering section, if disbudded as soon as possible to a single flower on a stem, will produce from ten to twenty flowers, perfect in form and large as Dahlias. Plants of this stamp are much more useful for general decorative purposes than those which are much larger, and the expense of growing them is probably not a tenth.

Cuttings may be inserted under hand-lights any time between March and June, potted-off singly as soon as struck, placed under hand-lights or in a cold frame again for three or four days, and then gradually inured to the weather, by which time, say in about three weeks or a month from the time the cuttings are put in, they should be potted into their blooming pots and placed outside, where they may remain till the blooms are partially expanded. In the absence of a glass house or pit they would expand very fairly in a cottage window, but light and shelter from rain and wind are absolutely necessary at this stage if clean and perfect flowers are required.

This treatment also suits the eccentric-looking Japanese varieties, amongst which I think Fair Maid of Guernsey the most beautiful of all Chrysanthemums. Of course Florists would not agree to this, but there is no reason why they should have it all their own way.

Many of the Pompons in a mild autumn will flower very fairly outside, or placed where they can be merely sheltered from frost by boards or canvas, the wet not hurting them as it does the large-flowering kinds; but the Anemone-flowered section is much improved by glass.

Disbudding and watering should be attended to in the same way as is directed to be done when growing for exhibition, but the training is altogether different; the shoots are never turned back or twisted, but are allowed to grow in a more natural manner, and as the plants are grown so quickly and are never stunted, insects and mildew are generally unknown. Should it, however, be necessary to apply sulphur, it is best to mix it with water and apply it with a syringe.—**WM. TAYLOR.**

THE RUSSIAN TRANSPARENT APPLE.

HAVING received through the Editors of the *Journal of Horticulture* many inquiries relative to obtaining trees or grafts of the above valuable Apple, I regret that I am unaware that trees can be obtained from any nursery. I am cognizant that trees are purchasable under the names of White Transparent, Transparent Codlin, &c., and I know of many which have been bought under these names, but in no instance have they proved identical or of equal value with the real Russian variety. In order, as far as possible, to accommodate those requiring this Apple, I have communicated with a cottager in my native village with a view to purchasing grafts for distribution. Grafts, he informs me, are scarce, for even during the past season, when almost all other trees were barren, the Russian Transparents were so heavily laden with fruit that very little young wood has been made. He is willing, however, to send what grafts he has, and purchase others which both he and myself know to be genuine. I have offered to give sixpence each for grafts, and I am willing to distribute them at the same price, with the addition of two penny stamps per dozen grafts to pay postage. I will guarantee that the grafts are true to name, but beyond that I incur no responsibility, and cannot entertain any complaints as to their size, either as being too large or too small. As a matter of convenience the whole of the grafts will be sent to Mr. Wright, 41, Ashbury Road, Shaftesbury Park, London, S.W., who has kindly consented to distribute them (on receiving stamps) until the small supply is exhausted. As I have nothing to gain by this arrangement, my only object being to extend the cultivation of one of the most useful of Apples, the Editors will perhaps permit this announcement being made in their columns. The grafts will be posted in the same rotation in which applications are received, and stamps will be returned in full when grafts can be no longer supplied.—**J., Lincolnshire.**

ROSES ON POOR SOIL.

A CORRESPONDENT (page 8) asks for information concerning Roses which are to be grown in poor sandy soils and in a smoky atmosphere. He gives a list of the Roses which he has found answer in smoky neighbourhoods, but does not say anything of those he has tried on very sandy soil.

I do not think it is possible for anyone to have a worse soil for Rose cultivation than I have. Some years back I sent a sample to the Editors of the "Rose Journal," and they forwarded it to the Rev. C. P. Peach, who described it as the very worst he had ever seen. I also sent a hamperful of this miserable apology for soil to Mr. Rivers of Sawbridgeworth, who promised me to try what he could do with it. He potted some Roses in it, but his foreman when repotting forgot to leave those alone that were in my soil, so when I went to Sawbridgeworth I could learn nothing of the experiment.

My soil is mostly greensand and flinty gravel, which the people in Dorset call "riderspit." It certainly is the worst stuff I have ever seen. "Hercules" used to laugh at me when I spoke of my soil being bad. "What! A man show like you do, and then to pretend that he has a bad soil!—It is simply ridiculous." After a time, however, he came to see me and walked all round my place, his eyes here, there, and everywhere, never saying a word. Suddenly he halted and said, "Now I see that you have indeed a bad soil."

The question then arises, How with such a soil did I contrive

to show at all? Well, at first in the hottest time of my youth and when the Rose fever had its strongest hold on me, I removed the soil to the depth of 2 to 3 feet. Yes, and wheeled it away and brought the top spit of grass, not from meadows, for no one dare let me have that, but from the sides of roads. I mixed this with manure, and the Roses did splendidly. These were mostly on the Briar, plants purchased from the great nurserymen, and the year after I made the beds I showed in two classes (thirty-six and twenty-four) at the Crystal Palace (my *début* there), and I was placed first in each class. After a year or two, however, this soil became a little stale, and I found I could not afford to make Rose soil at the cost of about £1 for each square yard, so I was obliged to think of some expedient.

I had never given the *Manetti* a trial, and as many friends advised me that Roses would grow anywhere and in anything (Mr. W. F. Radclyffe asserting that they would grow even in brickdust), I bought a lot and tried them in a field of the very poorest soil in this poor county. Every plant died, and I was that year dependant upon the standards which were growing in the prepared soil for my show blooms. Still I was determined to try the soil again, but this time I selected an old pasture which forms a part of my glebe. It faces the south and has a low kitchen-garden wall at the back. I cultivated this and dressed it with pig manure, and I certainly expected to do something there. But last year I was very unfortunate. The plants grew uncommonly well and gave great promise of bloom, when one night in May a neighbour's sheep broke into it and ate all my young shoots, and put me back at least a month, and so made me too late again for the shows, and so I had once more to depend mostly on standards in prepared soil. This year I hope to have no such bad luck and to do something with these plants. I should strongly advise your correspondent to remove the soil if he only wants to grow a few Roses. If, however, he aspires to hundreds or thousands let him buy up all the road drift or pay some farmer to let him remove the grass at the sides of the lanes, mix this with manure, lay it on the sandy soil, trench deep, and plant. A certain amount of sand suits the *Manetti* very well.

During the summer I should certainly advise him to water both the roots and the foliage, for these hot sandy soils require a great deal of moisture. If he does this I think he will find that he can grow good Roses even in sand.—WILD SAVAGE.

I should like to supplement "SAND HILL'S" list of Roses by adding a few which have done well upon a sandy soil in the neighbourhood of one of our large manufacturing towns (Manchester). They are—Alfred Colomb, *Boule de Neige*, Charles Lefebvre, Dupuy Janain, La France, Marie Baumann, Madame Victor Verdier, Paul Neron, Princess Mary of Cambridge, and *Sémateur Veisse*. I could mention many others which will grow and bloom with more or less success. But in Teas, in addition to *Gloire de Dijon*, *Belle Lyonnaise* and *Homer* are the only two which do any good without protection.

While writing about Roses I should like to ask if there are two varieties of *Gloire de Dijon*? Messrs. Cranston & Mayos sent me some plants last season which are quite different from any I have ever seen, the young wood being of a deep red colour, very fine foliage, and the blooms are small but of a beautiful deep salmon colour. I have been told by a friend that there is a kind known as the red-wooded *Gloire*. What do the rosarians say?—J. B.

JAPANESE CHRYSANTHEMUMS.

I HAVE read with much pleasure the remarks of Mr. Moorman upon the Japanese Chrysanthemums, which I am pleased to see are gaining favour, and will come into general cultivation for their usefulness as decorative plants. My object in penning these few remarks is for the information of your able correspondent and other readers of this Journal, that the Japanese varieties can be grown into specimens in any trained form the cultivator may require for home or exhibition purposes. I will name a few that will make specimens which may be relied upon, as I have grown them, and which have been staged on the exhibition table and won the approval of Mr. Newton from the Inner Temple Gardens, London, who was a Judge at the Liverpool Chrysanthemum and Fruit Show. The first seven below have been grown into specimens, mushroom shape, 3 feet over—James Salter, Red Dragon, Comet, Elaine, Yeddo Lilac, Hero of Magdala, and Roseum Album. Fair Maid of

Guernsey, one of the best, will make a specimen. The following I have grown, but they are too stiff growers to make good-shaped plants—Dr. Masters, Wizard, Tassel Yellow, Regalia, Robert Fortune, Anarast, Prince Satsuma, Nagaaki, The Daimio, The Mikado, and Bronze Dragon.—W. BIGGS, *Sandfield Park*.

BRUSSELS SPROUTS.

A GARDENER to be successful must be prepared for all emergencies, and especially must have a full supply of the staple vegetables at their several periods of use. An unusually hot and dry summer has been followed by an unusual scarcity of Brussels Sprouts. The late planting of other greens, and the prolonged autumn, have resulted in a tolerably good supply of produce, but late-planted Brussels Sprouts have proved, as such planting always must prove, a failure.

For the production of "Sprouts" in great quantities and of the first quality a long season of growth is essential. In order to ensure this, and to have a supply of this esteemed vegetable as early as possible and irrespective of the season, I have for many years raised plants similarly to raising Cauliflower plants—that is, sowing the seed early in September and wintering the plants in frames, and sowing again in January in boxes, and transplanting the plants in a sheltered place to be ready for final planting in April or May. I have many times—indeed every year—found the advantage of that practice, but never more so than after hot and dry summers.

Autumn-sown Cauliflower plants are now fully to early. It has been impossible to prevent them from growing too freely, and there is a danger of many of them "buttoning." This emergency must be provided against by now sowing a pinch of seed under glass, and let me advise that a little seed of Brussels Sprouts be sown at the same time. It should be sown very thinly—I mean that the seeds should not be nearer than a quarter of an inch from each other; the plants will then come up sturdily, and will not damp-off as they do when sown thickly. The seed pans or boxes should be placed in a very light house or frame from whence frost is excluded. When the plants show their primary leaves they should be pricked out in other boxes. About March they will be stout plants ready for being planted at wider distances near a wall or other place where they can be sheltered with a spare frame-light, hand-lights, or mats. They will be of full planting size in May, and are certain to produce a valuable crop of Sprouts early in autumn. No more trouble is incurred in raising a hundred or more of these plants than in raising Stocks, Astras, or Lobelias, and the vegetables will be of far more value in due time than the flowers, more serviceable and more appreciated. In producing the best possible supply of Brussels Sprouts in the autumn and throughout the winter, the plants cannot be raised too early in the spring. I recommend, therefore, that a portion at least should be raised under glass in the manner described, and they will produce a crop which cannot fail to be extremely useful let the season be of whatever nature it may.—MARKET GARDENER.

TRAINING VINES—LATE-HANGING GRAPES.

The observations and suggestions by "A NORTHERN GARDENER" upon training Vines at page 549 of the Journal of the 28th of December, are most instructive. I never could conceive any common sense in growing Vines rods like broomsticks, denuded of branches and foliage, contrary to the natural habit of the Grape Vine itself. Of course there is a medium "twixt wild luxuriance and stunted growth," and that is a moderate extension by which fruit, leafage, and wood bear relative proportions, and thus preserve the health and symmetry of the parent stock, or Vine. Imagine the distortion of Vines, thickened in their upper length of rod, and spindle-shanked at the base of the bole, or with pot-bellies and drumstick legs. How can the circulation of the sap be equal and regular so as to feed branch, twig, leaf, and fruit alike of such Vines? The question is simply that of pruning and training, as "A NORTHERN GARDENER" evidently has perceived. I will relate my own experience.

A few years ago I erected a new viney some 25 feet long by 18 feet wide, the front lights of which I had constructed nearly 6 feet high from the border to the eaves of the roof lights, thus forming a glazed frontage on each side of the viney, along which wires were drawn from end to end horizontally, the wires of the roof lights being also drawn across the house, and not perpendicularly as is usual. My object was the

formation of a wired trellis on the front and roof lights upon which to train Vine branchlets, somewhat like a garden wall-fruit tree of pyramidal shape, broad at the bottom and gradually tapering upwards until at the top of the Vines spurs or twigs only grow. My Vines were planted and trained accordingly, and need it be said have grown as a tree ought to do, stout in the stems and branched as pyramids from bottom to top, each branch being allowed to carry three, two, and one bunch of fruit as its length and strength may indicate sufficient. The Vines are planted 5 feet apart, thus having 2 feet 6 inches branch space on each side of every Vine. The wood is clear nut-brown, and the eyes stand out like so many horse beans on the branchlets, which I shorten-back to about six, four, and three to two eyes, progressively upwards when pruned. Laterals are stopped as is usual, but not at less than two, three, or four leaves beyond the fruit, or if not a fruit lateral, four to five leaves from their base, just as fancy may incline for outline and necessary foliage. This system appears to answer my purpose, that of a medium extension. The fruit along the front lights, from the sun's rays being more oblique there than upon the roof lights, is not so highly finished as under the latter lights, yet is large and plump and full-flavoured. I am only an amateur growing half a score of Vines, and copying Dame Nature; but I have no doubt that this copy under "A NORTHERN GARDENER'S" hands would prove a success, perhaps initiate a new era in Vine culture.

Your correspondent S. M. L. Cakin, at page 557, may try Duchesse of Buccleuch, or Graham's Muscat Muscadine, or Chasselas Musqué de Sillery (Golden Frontignan), the last one Mr. Rivers's choice Vines, as a white or yellow Grape, and better graft or inarch, &c., than plant a young Vine: so, I think, Mr. W. Thomson, author of "The Grape Vine," recommends.

Very likely the Lady Downe's and White Frontignan Grapes have shrivelled for lack of moisture or nutriment in an inside border not mulched with horse manure, or fed with manure water sufficiently. Vine roots are the better for a run into an outside border for air and rain in proper season.—READER.

WELLINGTONIAS.

The inquiry of "What is the height and circumference of the outside branches of the largest Wellingtonia?" ought to evoke some interesting communications on the rapid growth of this remarkable mammoth tree, for its introduction to this country is of so recent a date that there cannot be any trees planted that are past the memory of the present generation.

When I was in the gardens of Poltimore Park during the years of 1861-5 there were growing in these princely grounds two Wellingtonias. The heights of these trees were not less than 30 feet—they might have been more, and were looked upon as remarkably fine and well-furnished specimens. One of them by some cause lost its leader, when the topmost shoot was tied upright to a stick, and when on a visit to Poltimore last autumn the leader was in no ways wanting; in fact the tree referred to was the better-grown specimen of the two, and I could not help admiring the symmetry and staleness of both; and I made a note in my pocket-book at the time—"60 feet or over." I had no means of ascertaining their exact heights. My impression was that they would possibly measure 70 feet in height, or even more. They are perfect specimens and well furnished to the ground; but it appeared to me that, owing to the excessive drought of the past summer, they had, in common with other trees, made less growth than usual, yet receiving no injury.

I have read somewhere that the raising of plants from part of the first introduction of the Wellingtonia seed was at the late Mr. Veitch's Exeter Nursery. This being so, and Lord Poltimore's grounds being in close proximity to these nurseries, and in which grounds all choice and rare Conifers found a good home, I think it more than probable the specimens alluded to were of the first batch of plants raised and planted in his lordship's gardens by the late Mr. Manning, who was for more than twenty years gardener there.

I have been told that the discovery of the first germination of seed in Mr. Veitch's Exeter Nursery was on a Christmas day, and that the first Wellingtonia planted out in this country was near the rockery in these nurseries under the direction of the grandfather of the present representatives of this firm. Whether this specimen is still to be found there I am unable to say. Perhaps some of your Exeter correspondents can supply this information. Although this might have been the

first tree planted out in this country, it is not therefore necessary it must be the largest or tallest, as different soils may make a difference in growth, a cool clayey bottom apparently suiting the Wellingtonia best.

I hope shortly to be able to give fuller information of these trees, as also several other fine specimen Conifers which adorn the noble grounds of Poltimore.—J. W. MOORMAN.

In answer to your correspondent we have here some fine specimens of the Wellingtonia gigantea. The finest is over 50 feet high and 90 in circumference, and 12 feet 4 inches in girth of the trunk.

I have enclosed a seed of the *Arancaris imbricata*, of which I have several seeds. Can you inform me if it is usual for the above tree to bear seed to perfection in this country? We have trees here which have coned for several years. One tree is showing at this present time a hundred blooms.—EDWARD COVENEY.

[Trees at Strathfieldsaye have coned freely for several years. Mr. Gordon in his "Pinetum" says that the seeds ripen at the end of March.—EDS.]

VENN'S BLACK MUSCAT AND DUKE OF BUCCLEUCH GRAPES.

"AN ASPIRING AMATEUR" (see page 553 of last volume) will do well to keep his aspirations in check in the matter of Venn's Black Muscat Grape; at least he should not aspire to plant it as a late Grape, for most assuredly it does not belong to that class. We have here three sturdy Vines of it, two of which have borne good fruit, the last having been sent to table early in December, but very badly shrivelled. Indeed the fruit began shrivelling before I thought it ripe; and this could not have been owing to bad treatment, as other kinds, such as Gros Colman, Burchard's Prince, Trebbiano, Mrs. Pince, and Gros Guillaume, growing in the same house and border, were in every way good, and kept quite plump and fresh to the last. Venn's Muscat is a free grower and fruiter, a rather shy setter, but of the most exquisite flavour; and from my first season's experience of it I should say that it is best adapted for planting in an early house, but amateurs of limited experience had better have nothing to do with it.

Duke of Buccleuch.—This was also fruited in the same house, and was ripe at least a week before Venn's Black Muscat, so that I am inclined to set the Duke down as the earliest Grape in commerce. The fruit was every way magnificent, some of the berries measuring over 4 inches in circumference; but it will not keep—at least it did not with me—more than three weeks after being fully ripe. So that this also must be classed as not adapted for an amateur, but it is the Grape for a market grower who is certain of a customer the moment the fruit is ripe. I may add, that though evidently it is a near relative of Golden Clampion, it possesses a better constitution and is not liable to be affected with spot; at least it was not so here, as Golden Clampion always was.—W. WILDSMITH, *Heckfield*.

In reply to "AN ASPIRING AMATEUR," I bought a Vine of "the Duke" when it first came out, and planted it in a viney in which there are eleven other Vines. The first season I did not expect a Grape. The Vine was pruned at the usual time, and I sent the top to a friend as something special, and he raised from it two strong canes. The following spring my Vine broke strongly, but not a Grape was produced. In the summer I called on my friend and inquired after the Duke, and there saw the two canes which had been forced with several others for first crop, but not a Grape was on either rod. We agreed to grow it on. The new wood was shortened to four eyes. It broke very strongly last spring, but did not show a single bunch. In July I again called on my friend to inquire of his success with the Duke, and his answer was, "Not a Grape, and I have turned it out." I allowed the two leading rods to grow, and in the autumn one was shortened to three eyes and the other was cut back to the last plump eye, leaving about 5 feet of well-ripened wood. I have again started the house, with what result I wait to learn. I find that the Duke requires slightly shading, as the sun scalds or burns its leaves.—Geo. W. GREENHILL, *Whist House, Ashford, Kent*.

"AN ASPIRING AMATEUR" asks for experience on the Duke of Buccleuch Vine. I have not had much personal experience with the Duke, but I have seen it as grown at Clovenfords.

From what I have seen there, and from what I grew of it last season, I would say Plant a Vine of the Duke, as I am confident it is one of the finest Grapes for invalids in cultivation. Its large berries, few seeds, and delicate flavour makes it suitable for that purpose. I may add that it kept plump with me three months after being ripe, which is another recommendation.—JAMES DICKSON.

SELECT VEGETABLES FOR SMALL GARDENS.

"A KITCHEN GARDENER" has rendered a service to many amateurs in publishing such a useful list of vegetables as that on page 3. It is a reliable list, for the vegetables named are sorts of proved worth. But little room is left for criticism with a view of making the list still more perfect, and what I have to say will be directed solely with that object in view.

In the list is one important omission, only two varieties of Broccoli are named—namely, Snow's Winter White and Walcheren, and the latter is more a Cauliflower than a Broccoli; in fact as a Broccoli it is of no service, but as a Cauliflower it is valuable. The list, therefore, contains only one real Broccoli, which is generally in use during December and January, sometimes lasting into February. Yet Broccoli must be had throughout March, April, and May. Three varieties which, if obtained true, will produce heads throughout that period are Adame's Early White, Wilcove Late White, and Cattell's Eclipse, which follow in the order named. Other varieties will also come into use during the same period. These I will not name, but will give advice that may be more serviceable. Every seedman or firm of reputation pay special attention to some few varieties of vegetables—pinning, as it were, their faith on the excellence of such varieties. Consult, therefore, the catalogue of your seedman, and select for the seasons required such Broccoli which are specially recommended for those seasons. Probably you will obtain varieties, under whatever name, which have been selected from the three I have named, or from others equally good, and you will be satisfied; but to order the veritable three you may not obtain the exact varieties which I mean. Does anyone whisper "dishonesty?" He need not do so. Dishonest seedsmen cannot long flourish now-a-days. The fact is Broccoli to preserve them pure require special care, and it amounts to an impossibility that anyone can give that care to every variety in cultivation: hence each grower selects a few which he can emphatically recommend, knowing that particular care has been exercised in the selection of the stocks and the growth of the seed. But to make doubly sure of a crop so important as Broccoli it is advisable to procure small packets of seed of six sorts rather than large packets of three sorts. There is such a confusion in the nomenclature of Broccoli that it is far more difficult to advise a selection than in dealing with Peas and Beans. Perhaps that is the reason why "A KITCHEN GARDENER" left late Broccoli out of his list.

I would say a word on Snow's Winter White Broccoli. It is one of the most important and valuable of early vegetables, and gives more satisfaction and causes more disappointment than almost any other—satisfaction when it produces heads, as it should do, in midwinter; disappointment when it does not "throw up" until spring. If there is one vegetable more than another to which the warning may be applied "Beware of cheap seed," it is to this Broccoli. If ever I see it offered at less than 2s. an ounce I regard the price as a "danger signal." The cheapest way is to give an additional price for a guaranteed packet. It is one of the vegetables worth buying true or not at all.

I will now turn to Cauliflowers. "A KITCHEN GARDENER" recommends Early London as being the earliest. It is not so. Early Erfurt, or selections from it sold as Dwarf Mammoth by the principal English seedmen, is in my experience the first and the best of early Cauliflowers. I have had seed direct from Erfurt, also seed of Dwarf Mammoth and Early London from English firms, and my verdict is as above given. By sowing Dwarf Mammoth and Walcheren in September and again as required in the spring, also one good sowing of Veitch's Autumn Giant in April, Cauliflowers may be had over as long a period as they are obtainable. Walcheren resists drought better than does Early London, and better than either does Autumn Giant.

The next omission to refer to is the "Winter Greens," or Kale. These are indispensable in every kitchen garden. I do not hesitate to say that the best and most useful of all is Cottager's Kale—the best in quality, the most productive, and

the most hardy. I have known all others killed by frost, also all Cabbages, Savoys, and Brussels Sprouts, while Cottager's Kale was uninjured. That was in 1860, when the thermometer was 6° below zero. I have ever since grown Cottager's Kale, and shall continue doing so as long as I am accountable for the vegetable supply of a garden. The Dwarf, or Tall Curled Scotch Kale, is also valuable, and Buda Kale is useful for its lateness. For sowing at the same time as the above for winter use Couve Tronchuda is a delicious vegetable. It is also as hardy as Savoys, the best of which are Tom Thumb or Early Ulm and Dwarf Green Curled. There is one other vegetable which should be named with every seed order however small—Rosette Colewort. Seed of this sown at the end of June or early in July will produce plants for planting closely together in vacant ground, and which will yield a supply of "Winter Greens" of the first quality.—AN OLD HAND.

EXHIBITING EXOTIC FERNS.

HAVING been sent for to this island (Isle of Man) for a six-weeks supervision by my doctor, a source of rejoicing to me is that my old favourite crocheted Ferns crops up; and as I have not been writing about them for a considerable time, let me hope that these notes may prove of utility to some young, or perhaps inexperienced, exhibitor, and if so the pains bestowed on their composition is at once more than repaid.

But first I would ask, How is it that this, to my thinking, exquisite tribe of plants is so sparingly exhibited by amateurs; and when staged, why are the specimens, with comparatively few exceptions, so very second-rate? My own idea is that societies do not encourage them enough in their schedules. I have heard people say, "Anybody can grow Ferns; they are as easy as A B C." My own experience leads me to a contrary conclusion altogether; and indeed if their cultivation is so simple, how comes it that I rarely find my favourites at any show displaying the perfection of high cultivation, discrimination in selection, and last though not least, in point of staging without a fault?

I do not propose now to touch upon the cultivation of Ferns, but to treat them purely as exhibition plants. I could say a word or two upon the queer way in which I see them judged here and there, but not now. Most good judges of stove and greenhouse plants think, no doubt, that they are quite competent to judge Ferns. I entirely disagree, however, with any such notion. To enable any man to judge Ferns without the reasonable danger of making mistakes he ought to be thoroughly conversant with the not unrequited intricacies in their cultivation, and also with their comparative rarity or otherwise in this country. Judging them, as is often the case, merely by their *tout ensemble* is entirely wrong. Every point (I mean condition, which is high cultivation, quality, equality, and so on) for and against each individual plant should be minutely considered and weighed, and then the sum total made up.

One rarely sees now in the schedules of any society more than one group provided for of six, eight, or nine plants at the outside (stove and greenhouse plants and Orchids we often find in tens, twelves, sixteens, and twenties). We need to have a class for twelve at the Provincial Royal, and a silver medal was awarded, together with the money, to the gainer of the first prize; but just now such things are numbered with the past, not, I hope, for ever.

In my opinion at every show claiming to hold a high position one group of twelve or more Ferns should always be provided for, with, of course, others of say six or eight; and I would preclude exhibitors from either entering for or competing in more than one class, as by that prudent course you give to others the chance of winning a first or second prize, and I know there are many would-be exhibitors who calculate beforehand that at this or that show "Mr. Smith and Mr. Jones are always first and second," so others can only at the best be third, or not even that, and so, quite discouraged, they leave the plants at home, not relishing what by them is considered a discreditable position in the prize list. Now, I would far rather be a good third at a fine show than a bad first at a second-rate one with nothing below me worth defeating; for where is the honour in the last-mentioned case? If, however, a further chance were provided in the shape of another group of six or eight, and if (as I contend should always be done) exhibitors were precluded from entering for or competing in both, probably several young, or it may be entirely fresh, aspirants for fame eagerly enter the lists, and the result is a lively, keen, and much-to-be-desired competition.

Again, much monopoly is a great evil. This I have long felt to be true; it dispirits and scares away many exhibitors, and perhaps if a handicap could satisfactorily be devised that improved results would be obtained.

I am not a great advocate for mixing Tree and other exotic Ferns together at shows, because I consider it is wiser to have the former exhibited by themselves; and when we see, as we often do, three or four monster specimens with long stems put up in groups of six, eight, or nine, it is not easy to find others of equal proportions to go along with them, and so sometimes a very incongruous and extremely uneven lot is staged—giants and dwarfs in close company! Take as one example a fine *Dicksonia antarctica*, with a 6-foot stem and a head perhaps 12 or 14 feet in diameter, and a *Todea superba* not more than 3 feet over and a few inches high only from the top of the pot.

Tree Ferns are noble and magnificent objects, very stately and imposing. That I readily admit, for I grow many of them; but from the comparative ease of cultivating them they would not weigh much with me were I judging, and I should certainly award the palm to a fine group of eight or nine evenly-matched specimens, distinct in species (not merely in variety), highly cultivated, fresh, bright, vigorous, and healthy, the perfection of good staging (a point sadly neglected by many now-a-days) in preference to another, though much larger, composed of enormous Tree Ferns and *Gleichenias*. Give us one good large group, at any rate, limited to one plant of each species, and the overwhelming advantage at present enjoyed by those who, like myself for instance, revel in a lot of fine *Gleichenias*, those invincible Nelson-like heroes to a judge's eye would be, most properly, done away with. I once asked an old judge how many *Gleichenias* I ought to put in a group of eight Ferns. "How many?" said he. "Why eight, of course, if you have them." Now I had them, fine plants, distinct species too. What a wonderful sight they would have been; they were every one pictures of health and beauty; but yet I dare not stage them, and if I had done so, greatly as they might have been stared at and admired, it is more than doubtful whether they would have been placed first, though perhaps worthy of even the Lindley medal.

Let me here name twelve exotic Ferns to the notice of some young exhibitor, which I consider a first-rate selection, and which, if staged thoroughly up to the mark and of goodly proportions, would be, in my bold to say, nearly invincible. Each is a distinct species, and the monster Tree Ferns are left out. *Gleichenia rupestris*, *Cibotium Schiedei* (not a Tree Fern), *Davallia Mooreana*, *Adiantum Farleyense*, *Todea superba*, *Brainea insignis*, *Platycterium grande*, *Lomaria zamickelohi* or *cyadefolia*, *Leucostegia immersa*, *Chelanthus elegans*, *Goniophlebium subarcticulatum*, and *Pteris serrulata major magnifica*—a truly goodly company, gems of the aristocracy. The last-named is a Fern hardly known, yet richly deserving the title "magnifica," so broadly and superbly it is crested. My own plant is some 4 to 5 feet high and as much in diameter, and is a beautiful object just now, as handsome and graceful as need be; it is bound to make its mark some day. Now put with these, for the purpose of completing, a fine group of, say fifteen, *Dicksonia antarctica*, *Cyathea medullaris*, *Dicksonia squarrosa*, *Cibotium regale*, and *Cyathea Burkei*, and I defy any man to find a more perfect lot.

I come now to watch you stage, say, eight of them. Let me here first warn you, whatever show you propose going to, invariably to take your best plants. Do not imagine that this or that lot are quite weighty enough for your adversaries, inasmuch as Mr. Jones or Mr. Smith are sure to "turn up" at the last moment with the "big Farleyense" so dreaded by you—the finest plant in the country—as you find to your dismay when it is too late. Always take your best with you. If you win easily—a mere walk over—the victory is the more decisive; if closely run, and you win notwithstanding, your quiet satisfaction is of course the more enjoyable.

Now then, begin your staging; it is quite time. Mr. Smith, whom you dread most, has already finished his lot. They are, of course, "nowhere;" but, by the way, you notice that he has put a young fresh *Gleichenia*, say 3 feet in diameter, just in his front row, making it his centre plant. He has another 6 feet through in his van. A sly dog that Smith! You know you left your best, 7 or 8 feet over, in splendid condition at home, as it would not be wanted. As soon as your back is turned, and precisely at the critical moment, before the judges come in, Smith, finding himself too closely run, quietly trots to his van, exchanges the dwarf for the giant *Gleichenia*, and you are much surprised when you return, in order to ascertain the

result of the judges' fiat, to find that you are "second" only, and your "friend," the artful dodger Smith, "first!"

But to return. Come along, and stage your eight. Now, do not be content with simply placing your plants down in double rows of four (as many do), with your best specimen in front, exactly in the centre, to catch, as you imagine, the eye of the judges, and so insure your being first. They will not look well that way, but, on the contrary, very prim. Take your largest plant, and put it in the centre of the back row on a large pot, so that it may stand rather higher than its right and left-hand neighbours, and leave a moderately wide space between the three. Now, put two more in a second row, between, so to speak, the plants behind, and to hide the empty spaces. Your front row can then be easily managed; very similar to the back one, only drawn in slightly the two outside plants. Now gently tilt the whole lot, so as to produce one solid graceful sea of lovely green waving fronds, thereby hiding, though of course as unostentatiously as you can, the pots or tube (these must be scrupulously clean), then take your labels, write them in a bold legible hand (the plainest and least expensive method is always the best), place them lightly in the elit of the sticks (these too must not be clumsy unpainted abominations so often seen, but thin and neat-looking), push each down firmly into the soil at the back (not in the front, or centre, or anywhere you can, which I often see done), adjust your private "number card" in front, and quietly wait your fate. It is not easy to estimate the great importance of each of these minor details, which you perhaps may think insignificant, but remember that the keen eye of an old experienced judge looks not merely at the plants, but also to see whether the group is, as a whole, slovenly staged or thoroughly up to the mark; and when your neighbour's plants, say your friend Smith's if you like, are evenly balanced with your own, and it is found perhaps not easy to decide between them for premium honours, then it is that the (by you) despised details of each lot are weighed deliberately by the judges one by one, such as the clean pot or tub, the masterly tying-out, the neat stake, the tidy and legible label, and also that somehow or other indescribably wonderful finishing touch to his pet, which the old hand learns by long experience to "put on" at the last moment, with such a fatal result to you; and whilst the first-prize blue card (taking with it too that long and much-coveted silver medal) hangs elegantly though modestly from Smith's "despised lot," you are obliged to be content with the, to your mind, humiliating colour on which you find the sickening words "second prize." Nay, further; you must also endure the unpleasant reflection that the plants which could have landed you easily at the goal are snugly at home, some 150 miles away, a fact, too, known perfectly by your adversary, who is watching you with grim satisfaction round the corner, and laughing in his sleeve at your unmistakable astonishment, consternation, and discomfiture.

—T. M. SHUTTLEWORTH, F.R.H.S.

N.B.—From first to last there is not a word in these notes containing a double consonant, except, of course, the names of the Ferns. I undertook to try and do this to please a valued friend of mine, who thinks that double consonants ought to be entirely done away with in writing the Anglo-Saxon language, and who rather doubted, I think, whether I could write so long an article as I contemplated without using some few words containing the obnoxious double consonants.—T. M. S.

PROPOSED SHOW OF CARNATIONS AND PICOTEES.—The undersigned desire to state that, in consequence of the uncertainty as to the action of the Royal Horticultural Society, they intend to promote a Show of Carnations and Picotees to be held in London during the season (July), and they will be glad of the co-operation of their brother florists in the work. A meeting to arrange preliminaries and commence a subscription for the needed prize fund will be held at the rooms of the Horticultural Club, 4, Adelphi Terrace, Strand, on Wednesday, January 31st, at one for two o'clock, when the attendance of all interested will be greatly esteemed.—CHARLES TURNER, *Royal Nursery, Slough*; JAMES DOUGLAS, *Loxford Hall Gardens*; E. S. DODWELL, *Larkhall Rise, Clapham, S.W.*

SOME SPECIES OF PRIMULA.—No. 2.

PRIMULA CORYMBOSIDA.—The normal species is a native of Siberia; it is well adapted for pot culture, and if a mass of it is grown in a shallow pan the numerous umbels of bright rose-coloured flowers have a very pretty effect. I have grown it out of doors in the neighbourhood of London very success-

fully; but to grow it well the plants ought to be renewed every three years from seed. I sow the seeds in April or May in a pot, placing in a gentle hotbed, and when the young plants are large enough to handle they are pricked out an inch apart in boxes containing good soil—loam three parts and leaf soil one part answers admirably. In August or September the plants will have become sufficiently large to plant out in their permanent beds. The object of planting at this time is that they may become established before the winter. The soil ought to be moderately rich, but should not contain any crude manure, which causes some of the plants to canker. I do not know how they would do in soil composed entirely of peat, but they do well in half peat and loam, or in a soil composed entirely of loam. They will flower well the following season, and also the next year, and probably a year more; but after that they decline in vigour and do not give satisfaction. It is a lovely plant for the rock garden; I had one in a sheltered position which grew and bloomed well annually for nearly a decade.

P. C. AMGENA and varieties of it are beautiful objects for the decoration of the greenhouse or conservatory in April. I have not tried any of them out of doors, but they are so very nearly allied to *P. cortusoides* that probably the same treatment out of doors would answer for them. When grown in pots they are very liable to be attacked by red spider, and if this gains upon the leaves they soon become sickly and ultimately perish prematurely, which seriously diminishes the vigour of the plants. They do best in a well-drained compost of turfy loam four parts, leaf soil one part, a little decayed stable manure, and sand is added, if necessary, to keep the compost open. From the time the crowns begin growing until the first flowers open early in April, the pots must be kept near the glass to prevent the leaves and flower trusses from being drawn up weakly. They also require plenty of air, but they are impatient of being exposed to scorching sunshine about the end of March or early in April, and a thin screen of light shading thrown over the glass for a few hours at midday is very beneficial. When the flowering period is over remove the plants to a shady position. They do not require much

water, but must not be "dried off." As the old leaves fade they should be removed, continuing to water just enough to keep the soil moist. About September all the leaves will have been removed, and the plants should be shaken out of the pots and repotted. —J. DOUGLAS.

LATE-HANGING GRAPES— VINE MANAGEMENT.

At page 557 Mr. Cakin asks for the advice of some of your Vins-growing correspondents in connection with his Lady Downe's and White Frontignan Grapes. Every competent Vins-grower knows that imperfectly ripened Grapes will not keep so well as others which are fully matured. Proof of this Mr. Cakin has in his own greenhouse, as he says that "not a few of the Hamburgs are still hanging in excellent condition."

My opinion is, that the Vines have been kept too dry during the time the Grapes were swelling, and in September when the fruit was colouring they have had too much atmospheric moisture with a too low temperature. Proof of this was the "tiny drops of moisture, like dewdrops on some of the berries in the morning," a sure indication of a too low temperature before the Grapes were thoroughly ripe. This sudden check no doubt was the cause of the shrivelling. To prevent a recurrence of the evil

explained of, my advice to Mr. Cakin is that as soon as the foliage is off the Vines to prune them immediately, rubbing the stems well with the hand to remove all loose bark from them, then with a hard brush give all the wood and glass a scrubbing-down with a strong solution of hot water and soft soap, giving the Vines a good scrubbing with the same solution, making sure that the water is as hot as he can bear his hand in it. Finish off with giving the wood, glass, and Vines a vigorous syringing with pure hot water, which takes off all the soapy matter and prevents dust from adhering to the Vines and other

FIG. 2.—*PRIMULA CORTUSOIDES*.

parts of the house. This done, give all the walls of the house a whitewashing with hot lime, then remove 2 or 3 inches of the surface soil of the borders, taking care not to injure the roots, and give a top-dressing of something like the following:—To six barrowloads of good turfy loam add one of half-

inch bones, one of wood or stick ashes, one of horse droppings, and half a bushel of soot. This compost may be laid all over the border to the depth of 3 or 4 inches, and forked slightly in, taking care not to injure the roots.

Next season be careful with firing and airing, never allow the roots to be too dry while the fruit is swelling. Guard against a stagnant atmosphere, as the Vine does not delight in an atmosphere overcharged with moisture, neither in one too dry. To this pay particular attention. Three or four times before the fruit shows signs of colouring give good soakings of liquid manure. When colouring commences keep-up the required heat and never allow the houses to be kept close, but allow a little air at top and bottom (according to the state of the weather), night and day. If these instructions are attended to I am certain that Lady Downe's will be grown in a satisfactory manner provided the border is good.

In regard to White Frontignan my opinion is, that it should not be rooted out, but inarched with Buckland's Sweet-water, which is a Grape that will give satisfaction. —A GRAPE-GROWER.

[The practice here detailed is from one who has won a foremost place amongst British Grape-growers.—EDS.]

EARLY WRITERS ON ENGLISH GARDENING.

No. 25.

RICHARD PAYNE KNIGHT.

HAVING written in a recent *Journal of Humphry Repton*, we may now record a few observations on the gentleman who advanced still further towards copying nature in garden designing.

After studying the writings of the several partisans we have been able to draw but one conclusion, which is, that the principles of Knight and Price are correct if impartially considered, and have been acted upon by the general consent of modern designers; nor can there be a greater proof of this position than that in his maturer practice Repton acted upon them himself. They differed in no one point of importance, that we have been able to discover, as to what constitutes beautiful points in a landscape: of course they agreed that such should be imitated; and we have read not one passage in any of their writings which will warrant the conclusion that, if assembled together, there would have been a dissentient voice to the observation of Price, that regular beauty and utility must not be neglected in the pursuit of the picturesque, for that would be opposed to the dictates of common sense.

Richard Payne Knight was the eldest son of the Reverend Thomas Knight, of Wormesley Grange, in the county of Hereford, and was born in 1750. He was a weak and sickly child, and his father did not send him to school, or suffer him to learn either Greek or Latin at home. Soon after his father's death, which took place in 1764, he was sent to a grammar school in the neighbourhood, where he made a very rapid progress in the Latin language. After leaving school he did not go to a university, but at the age of eighteen he commenced the study of Greek, which he pursued with great diligence, and which

became one of the chief occupations of his life. Shortly afterwards he visited Italy, principally on account of his health; and here he seems to have formed the taste for the fine arts, and especially for the productions of the Greek sculptors, which was his most prominent characteristic. Subsequently to his father's death he inherited the large estate of Downton, near Ludlow, from his grandfather, on which, after his return from Italy, he built a mansion, and he devoted much time to improving and ornamenting his grounds. In 1780 he was elected to serve in Parliament for the borough of Leominster, and in the following Parliament of 1781 for the borough of Ludlow, for which he continued to

FIG. 4.—RICHARD PAYNE KNIGHT.

in Cornwall, Bishop of Worcester. In 1794 he published the "Landscape," a didactic poem in three books, addressed to Uvedale Price, Esq. This poem contains many precepts, marked by sound judgment and good taste, on the subject to which it relates. It appears from the preface to Mr. Price's "Essay on the Picturesque" (published in 1794), that Mr. Knight proposed to Mr. Price that the papers written by the latter on rural improvement should be published with his poem of the "Landscape," in the same manner Sir J. Reynolds's notes were published with Mr. Mason's "Du Fresnoy;" but that the proposal came too late to enable Mr. Price to accept it.

Deprecating the formal style of laying-out the grounds around a mansion, Mr. Knight describes it as the style which

"bade the stream 'twixt banks close-shaved to glide;
Banished the thickets of high-bowering wood,
Which hung reflected o'er the glassy flood.
Dear peaceful scenes, that now prevail no more,
Your loss shall every weeping muse deplore!"

Fossil Plants.—The large number of fossil plants brought home from Greenland and Spitzbergen by the two Swedish ex-

peditions of 1870 and 1872 have been carefully examined by Dr. Oswald Heer, and they appear to show important light on the geological development of the plant world. An account of his study of the remains from the chalk period appears in a recent number of the "Naturforscher," and in the summary of his results Dr. Heer points out that the facts are against a gradual imperceptible transformation of plant types; from the upper chalk the dicotyledons appear suddenly in great variety without any transition, whereas other forms at this period wholly disappear from the scene. Further, these researches make it very probable that a whole series of genera have had their origin in the Arctic zone, and have thence "radiated" southwards. Lastly, Dr. Heer shows that the facts at present known of plant paleontology do not point to any alternation of climate or repeated ice-periods in these regions, a view which has also been developed by Professor Nordenskjöld.—(Nature.)

JUSTICIA FLAVICOMA.

THIS is a most useful plant for the decoration of the greenhouse or conservatory at this season of the year, its yellow flowers contrasting well with scarlet bracts of the *Poinsettia pulcherrima*. Plants of the *Justicia* from 1½ to 2 feet high dotted amongst plants of a dwarf habit have a very striking effect, and never fail to attract the attention of visitors.

The plants require a little rest after flowering, and in the spring I cut them down and encourage them with heat and moisture to break, when the old soil is shaken away and they are repotted. They are then encouraged to grow freely during the summer months, so as to make strong plants by autumn, and according as they are required I introduce them to stove heat; and when they come in bloom they are taken to the greenhouse or conservatory, and a very pleasing effect they produce, and continue a long time in beauty, which a great many of the other species of *Justicia* do not. It is very seldom one meets with the above old *Justicia*, but I think it inherits properties which might entitle it to more general cultivation.—J. A., Hill Grove.

STIRLING CASTLE APPLE.

For dwarf trees especially I cannot recommend a more suitable Apple than this. It appears to me to have all the good qualities of the Hawthornden—earliness, productiveness, high culinary quality, and compact growth, yet without the proneness to canker which renders the Hawthornden unsuitable to many soils. Were I planting dwarf trees largely with the view of deriving the earliest profit by the sale of their fruit, I should certainly have a good number of Stirling Castle. In a long row of trees in twenty-five varieties, the three which have proved the most valuable by their free and constant bearing, and the excellence of their produce for culinary purposes in the autumn, are Lord Suffield, Stirling Castle, and Cellini, coming into use in the order named. I am scarcely able to say which of these three I have found the most serviceable for home use. For travelling the Stirling Castle is the best, not bruising so much as the other sorts named. The soil of the garden is rather light, and Hawthornden cankers excessively. In this soil Stirling Castle requires no root-pruning and but little summer-pinching, but grows into a natural and fruitful bush which anyone can manage. Does "WILTSHIRE RECTOR" grow this excellent culinary Apple?—B. B., Berks.

STANDARD HELIOTROPES.

EVERYBODY agrees that sweet-scented flowers are desirable in the flower garden, but everybody does not agree to put them there, because as a rule sweet-scented flowers are not showy or do not last in good condition throughout the summer, and are consequently almost inadmissible to the formal garden. Were a highly-coloured *Heliotrope* which was at the same time sweet and free-flowering to present itself we should never again lack sweetness on the parterre, but for the present we must make the best of such as we have.

If the *Heliotrope* is not showy in colour it can be grown into a very pretty formal shape as a standard, and is then admissible to the most formal of gardens for the centres of circles or long rectangular beds. I used many of them in this way last summer alternately with standard scarlet *Geraniums*, and they were greatly admired both for their beauty and perfume.

Cutting struck now and grown-on in an intermediate temperature through the winter, each trained to a straight stake with

a wire hoop at the top, will make plants of almost any desirable size by June, when, if planted out carefully, they will flower abundantly till the frost put an end to their existence. This did not happen till the 1st of November in the past season: they were certainly as beautiful on the last day of October as they were any time during summer. They had half-globular heads about 2 feet through, and were encouraged to assume a partially drooping form. Any strong-growing variety will do for the purpose; but one I met with last autumn at Ashton Court, called Miss Lewington, will I think prove the best, it being a vigorous good-habited grower and of a brighter colour than any variety I have hitherto seen.

Standard *Geraniums* do not form very good heads in one year, but they lift well in autumn (which *Heliotropes* do not), and they improve as they grow older.—Wm. TAYLOR.

MARÉCHAL DE COUR PEAR.

MANY useful fruits have been mentioned in your columns during the planting season, and information of great value has been communicated. Acting on your advice, some years ago I planted at the gate end of my house the Pear above named, and I have had good reason to be satisfied with the result. I have not only won local prizes with fruit from this tree, but have been successful with it at one of the greatest shows of the Royal Horticultural Society. This Pear appears to me to possess a more than usual number of good properties. It is of noble appearance, of splendid quality, productive, and hardy. It ripens early in November, and is esteemed as the best Pear in its season. I have many applications from would-be purchasers, who pass by and admire the fine specimens which annually clothe the wall whereon the tree is trained. The aspect is nearly due east. To anyone having wall space for a tree and desiring superior Pears in November I say, Plant *Maréchal de Cour*. I have young Pear trees growing as pyramids, and amongst them the *Maréchal* is most promising. I have also seen it very fine in other gardens in this district.—M. A., Lincolnshire.

ASPECTS OF NATURE—DECEMBER.

"O, Winter! ruler of the inverted year,
Thy scatter'd hair with sleet-like ashes fill'd.
Thy breath congeal'd upon thy lips, thy cheeks
Fring'd with a beard made white with other snows
Than those of age, thy forehead wrapp'd in clouds,
A leafless branch thy sceptre, and thy throne
A shivering ear indubbed to no wheels,
But urged by atoms along thy slipper's way—
I love thee, all unlovely as thou seem'st,
And dradest as thou art."

DECEMBER, although the last, and generally looked upon as the most barren month of the year, has, flowerless and almost leafless though it be, an aspect of cheerfulness for those who seek Nature in her most favourite haunts. The forest trees are bare, and only the irrepressible Primrose and equally hardy Violet among spring flowers dare show their bright fresh foliage on sheltered banks, where they peep forth from among the dried and rustling grass, forming an almost spring-like contrast to the scarlet berries of the Cuckoo-pint or Wake Robin, which may still be found in many places, although they have but little time to remain with us; for even should bitter frost and heavy snow not hasten their disappearance, they will fall from the stem into the earth beneath to give us fresh plants for another season. But the Arums are not the only plants with berries of gaudy hue making spots of brightness in the landscape; the essentially winter plant the Holly, should at the beginning of the month—before violent hands have been laid upon the shrubs and they have been divested of half their glory, their berry-laden branches—be in the plenitude of its beauty; and this season, which has been exceptionally mild though wet, the dark sombre foliage of the Yew is still relieved by the rosy pink of its wax-like berries, many of which the birds have as yet spared.

Of plants made beautiful by their fruit at this season a charming garland might be formed. Those we have already mentioned, the Arum, the Holly, and the Yew, would be sufficient for brightness, while the Ivy, the Privet, the sacred Mistletoe, the evergreen Thorn and others would serve for contrast. But it is not alone in the berries or in the glossy varied foliage of our evergreen trees and shrubs that beauty may be found. The Mosses and Lichens attract attention at this season, not only because they are in the fulness of their beauty, but because at this time they are less hidden by larger

and more attractive plants. Small and inconspicuous to ordinary observers, the Lichens and Mosses gain their full meed of admiration from the student of Nature, who sees within their tiny cups and the manifold diversity of their miniature forms a marvellous instance of the limitless wonders of Nature. This is the season also of their fructification, when the exquisitely delicate greens and greys, so distinctive of these families, are in many instances relieved by thread-like rosette stems and blossoms, if we may so term them—so lilliputian as to appear like tinted hairs. The old orchard trees in Devonshire are so covered with grey Lichens that, save on the youngest wood, the bark of the tree is never seen; and this is the time, too, when in Worcestershire and other counties the *Mistletoe* in its peculiar hue of faded green, appearing like Lichens of a larger growth, is cut from the Apple trees on which it grows so abundantly.

When, as so frequently of late,

"The rain and wind best dark December,"

the wintry aspect of Nature is almost forgotten, the grass remains so fresh and green beneath repeated showers that a few hours' sunshine makes us almost believe it is spring, even while yet the winter solstice has not been passed. But the old adage says,

"When the day lengthens
Then the cold strengthens."

and so we may still believe that Winter in his old-fashioned garb of frost and snow will yet come to us. But whatever the weather—boisterous wind and driving rain, hard frost and deep snow—December brings us to the end of the year, and with the opening days of January we feel a change, too subtle to be seen, in all around. It is, as it were, the mysterious voice of Nature which speaks to our inner consciousness of reviving life. Day by day a few more minutes of light, and day by day we breathe an atmosphere which inspires hope, for the darkest days are past and the months to come are full of promise.

"These as they change, Almighty Father, these
Are but the varied God. The rolling year
Is full of Thee.
In winter awful Thou! with clouds and storms
Around Thee thrown, tempest o'er tempest roll'd,
Majestic darkness! in the whirlwind's wing
Riding sublime, Thou bidst the world arise,
And humblest nature with Thy northern blast,
Mysterious round! what skill, what force divine,
Deep felt, in these appear! A simple train,
Yet so delightful, mix'd with each kind art,
Such beauty and beneficence combin'd!
Shade, unperceived, so soft'ning into shade;
And all so forming an harmonious whole,
That, as they still succeed, they ravish still."

—T. S. J.

MRS. PINCE'S BLACK MUSCAT GRAPE.

My experience of this Grape coincides with Mr. Anderson's given on page 516. My Vines of it are all grafted, chiefly on Black Hamburgs. It is a Grape evidently requiring a long season to ripen thoroughly, and hence should be started earlier than Lady Downe's or Black Alicante. I have never seen it really well coloured, there being always more or less of redness at the stalk end of the berry. In appearance it cannot compare with Alicante, but is quite equal to it, if not superior in keeping qualities, while in point of flavour it is far before it; in fact, so far as my experience goes it is the finest flavoured of all late-keeping Grapes. I have had it in good condition until April. I find it sets freely in a low temperature, if care be taken to shake the bunches or draw the hand carefully over them once a day when in bloom. I have tried it in several varieties, but always obtain by far the best coloured and finest fruit off a Vine growing within 3 or 4 feet from a hot-water boiler, where in growth the roots always have a very considerable amount of bottom heat. In this position the Vine of course requires abundance of water.

With regard to late-keeping Grapes generally, I give the first place to Lady Downe's, and putting aside the question of bloom and colour, the second place to Mrs. Pince, Black Alicante standing third on my list. If appearance alone must decide the merits of the last two, Mrs. Pince must necessarily occupy the third place.—J. E.

PREPARING POTATOES FOR PLANTING.

I CANNOT quite agree with "A NORTHERN GARDENER" (see page 528) in his mode of preparing the Potato before planting. He advises that the sets should be carefully looked over and

set upon their ends in a light place, so that the tubers may be able to strengthen their growths before they are planted. Now my opinion about this is that if those Potatoes, such as early kinds, were at this period of the year carefully planted on a warm border at the depth of 6 inches, that the tubers would grow quite as strongly on the ground if not stronger than it placed in the light.

I think we should have better crops if we planted earlier in the season than is usual. They should all be in by the latter end of February, and I advise that we grow more of the kidney and what we called the second early kinds, and not so many of the late sorts; for I am of opinion that if more of these kinds were grown we should not be troubled nearly so much with the disease as we have been of late, for we should be able to have the Potatoes out of the ground, dried, and stored away before the autumn rains set in. During the past season all the early sorts of Potatoes, not only when dug turned out a fair crop, but not a bad one was seen amongst them, but the later kinds when taken out of the ground were quite half of the other bad. That is why I advocate growing more of the earlier kinds.—A YOUNG AMATEUR.

EARLY-FLOWERING AZALEA INDICAS.

PLANTS flowering in advance of the generality of their kind are very valuable, inasmuch as they are more readily forced, and by their earliness contribute to producing a long season of bloom. Irrespective of forcing, Azaleas may commence flowering in February and be continued to June by a selection of early, midseason, and late varieties, ordinary greenhouse treatment being given the plants.

The early-flowering varieties are the most desirable for forcing; they are more readily excited into growth, taking less time and a lower temperature to have them in bloom by a given time than the midseason kinds. The new year usually brings along with its festivities a great demand for flowers. None are more desirable than Azaleas both as plants for decoration or as affording flowers for cutting. Small standard plants a foot to 15 inches high, with heads as round as a ball, covered with flowers, are admirably adapted for table decoration. Pyramids are certainly very gorgeous when in flower, and exhibit great skill in training; but why not have variety in form? Why not more plants be allowed to assume their natural bush-like habit? A half-ball is no despicable form of Azalea.

Double flowers as a rule are not only more beautiful but more lasting than singles: hence their greater value for cutting. In Azaleas we lose in doubles the beautiful marking of the singles, the doubles being mostly selfs or their marking and shading are indistinct. Nevertheless the doubles have a fullness and an endurance fully compensating for any loss of marking.

Amongst the best of the early-flowering Azaleas are *Narcissiflora, double white, very profuse-flowering, and certain; *Boreig, double white, very fine and equally free; Bernhard Andreas is another fine double white; *François Devos, double deep crimson, is of capital habit and very free; Roi des Doubles, double rosy carmine, very free; Roi des Belges, double bright red; and *Amélie, violet purple, small, semi-double, well known, excellent for forcing. In singles we have *Alba, pure white; *Fielder's White, Magnol, rosy salmon; Madame Van Houtte, white, flaked rose and crimson; Roi d'Hollande, deep red; and *Vittata elegans, white, red edges.

Those distinguished by an asterisk are fine for forcing, and ought to be grown in quantity by those having flowers largely in demand. They can be had in flower at the duller season with slight forcing.—G. ARREY.

TABLE DECORATION.

THE following arrangement came under my notice at a dinner table the other day, and I write, as I consider it worth copying. The foundation of a centre bouquet at table was a plant of ordinary Maidenhair (*Adiantum*) in an 8-inch pot. The pot was screened by one of the expansible wooden screens, and among the fronds of the plant were inserted, at the height proper to be effective, flowers tied to sticks or wires concealed by the Fern, notably Allamanda Schottii, Lapageria rosea, Poinsettia pulcherrima, a solitary Rose, *Primula sinensis*, various Geraniums, and other flowers not so noticeable. The effect was charming, the more so as the fronds of the Fern were naturally disposed more gracefully than they could have been done had

they been culled and inserted among the flowers, and the plant itself was uninjured.—A SUBSCRIBER.

BEGONIA NITIDA ODORATA.

In reply to Mr. Seers I may say that I have this Begonia planted out in a narrow border against the back wall of a stove, the shoots being trained to a wire trellis, and are bearing panicles of flowers, than which few others at this season are more attractive. The plant in question was a year old when planted out in May last. It is now several feet high, and will go on growing and flowering continuously until it overgrows its space and becomes bare and leggy, when it must give place to a young plant. I grow all my Begonias for winter-flowering from cuttings struck in April, growing them on during the summer, and they bloom all the winter. They are not kept a second year, as young plants give finer flowers and fresher foliage. *B. insignis* is very free. It is now flowering, as also are the following species and varieties:—*B. Ingrami*, *Sanderiana*, *erecta multiflora*, *parviflora*, *Weltoniensis*, *fuchsoides* and *hybrida floribunda*. *B. manicata* is throwing up its great feathery forked panicles, which are very elegant whilst they last for vase decoration.—G. A.

MYOSOTIS DISSITIFLORA.

Not many gardeners, it is to be hoped, are without a stock of this charming Forget-me-not. Its worth is now well proved and its value admitted. The plants for early flowering should now be robust and about 6 inches in diameter. These planted closely in lines or beds will in the earliest days of spring produce an effect that will not be surpassed during the whole season of the year. But I allude to this plant now for the purpose of noticing its great value when grown in pots for indoor decoration. Plants for this purpose should be taken up and potted without delay. Already the flowers may be perceived in some of the shoots, and which may be injured by a possible visitation of frost and snow. These plants, if potted in rich soil and placed in a cold frame or on the shelf of a greenhouse, and kept well supplied with water, will produce dense masses of lovely colour in February and March, contrasting admirably with all kinds of Dutch bulbs, and rendering the conservatory specially attractive and enjoyable. I know of no plants which with equal ease and so much certainty produce such a chaste, distinct, and agreeable effect in the earliest months of spring as this charming Forget-me-not. It should be grown in quantity in all gardens where spring flowers are cherished, and especially should it be employed for indoor decoration.—A CONSERVATORY FOREMAN.

NOTES AND GLEANINGS.

We have had accounts sent to us from many places of the injury caused to garden crops by the excessive wet. Not the least of the inconveniences of the season has been the flooding of stakes and the extinguishing of fires, rendering other adjuncts necessary for the provision of heat. The most prompt and handy of these adjuncts are PORTABLE STOVES, which are made in metal and terra cotta after the principle adopted by the late Dr. Arnott. We have found by experience that these stoves introduced into forcing houses and tropical ferneries are of substantial value in keeping up the heat, and at the same time without injuring the most tender vegetation, provided—and this is of the greatest importance—that the elements of combustion are carried away by a pipe into the open air. A shallow dish of water placed on one of these stoves secures atmospheric moisture proportionate to the heat of the stove. One or two stoves of this nature should be had in reserve in gardens where the regular means of heating is liable to interruption by excessive rain or other causes.

The gentlemen recommended by the Council of the ROYAL HORTICULTURAL SOCIETY to fill the vacancies for the ensuing year caused by the retirement of Mr. Robert Warner, Hon. and Rev. J. T. Boscaaw, and Sir Trevor Lawrence, are Sir Charles Strickland, Bart., Mr. H. J. Elwes, and Mr. T. M. Shuttleworth.

—AN INSTANCE OF PEAR TREES RIPENING TWO CROPS OF FRUIT IN ONE SEASON has been communicated to us. The trees are standards in the garden of S. Lutwyche, Esq., Bramertons, Lower Tulse Hill; the variety Williams' Bon Cretien. From these trees the gardener, Mr. Gates, gathered the first crop at

the beginning of September of last year (1876), and in November he gathered a second crop from the same trees. The latter were quite ripe, and equal in quality but not in size to those of the first or principal crop. It is not uncommon for Pear trees to blossom twice a year, but it is a very unusual circumstance for them to perfect two crops of ripe fruit. The circumstance is no doubt attributable to the extreme heat and drought of summer ripening the wood prematurely, followed by the moist, mild, and prolonged autumn, which has proved in the case of these trees a second spring and summer. It will be interesting to note the condition of these trees during the next spring and summer, after having so clearly "lost their reckoning" in the past year.

—SPRING FLOWERS are welcome to all, and especially such which have long been familiar—the cottagers' flowers—Crocuses, Snowdrops, &c. These flowers are now showing their "grass" above the surface of the ground, and these established clumps if potted will force with the greatest certainty, and unfold their flowers in windows and green-houses some weeks before they would expand in the open air. It is not everyone who can purchase a supply of these bulbs "fresh from Holland" every year for forcing, but all who have them in their gardens may dig-up the clumps and place them in pots in light soil. All that is afterwards necessary is abundant supplies of water and the lightest position at command, and masses of purity and beauty will shortly be produced. Many humble dwellings may be made cheerful and many window-sills bright by these home-grown and home-forded bulbs. They are flowers, too, for the town as well as flowers for the country, and are so easy of culture that even a child may manage them. For miniature suburban green-houses these home-grown bulbs are very suitable.

—AS AN INSTANCE OF THE MILDNESS OF THE SEASON a Nottinghamshire correspondent informs us that he has the old Monthly China Rose flowering freely in his garden, and that he has lately gathered lovely blooms of Gloire de Dijon. He thinks these good old Roses worthy of being extensively grown as the hardiest and most persistent bloomers in cultivation.

—AT THIS PERIOD of the year when preparations are being made for the spring and early summer decoration of the conservatory, the value for this purpose of the EARLY-FLOWERING CLEMATISSES should not be overlooked. Plants of these Clematises in 8-inch pots, or even less, flower most freely and produce an effect which cannot be surpassed by any other plants. All that is required for success is that the last year's shoots be matured, and a viney being started will do the rest, for the steady progressive temperature necessary for the Vines is suitable also for the Clematises. A few which are suitable for early flowering are Albert Victor, lavender; Miss Bateman, white; Lord Lonsborough, mauve; Lady Lonsborough, silvery grey; Fair Rosamond, blush white, scented; Standishii, light purple; Stella, deep mauve; The Queen, lavender; and the double varieties Fortunii, John Gould Vetch, Lucie Lemoine, and Countess of Lovelace. No other conservatory plants can excel these in beauty during their flowering period, April, May, and June, according to the amount of forcing to which they have been subjected.

—PROMINENT attention has recently been given to the deficiency of colour of Mrs. PINCE'S MUSCAT GRAPE. There is reason to suppose that this Grape has been, as a rule, subjected to an extreme of cool treatment. When it was found that it would ripen without the high temperature usually given to Muscat of Alexandria, the fact was interpreted too freely, and Mrs. Pince was extensively planted in houses altogether too cold for its requirements. It is a Grape which is long in ripening, and if it is grown in a cool house the Vine must be started early with the assistance of fire heat in order to provide a long season of growth. It is a Vine, too, having small foliage, and should not be subjected to such close pinchings in summer as other varieties will endure without injury. With a higher temperature and a longer period for maturation, and a more liberal allowance of foliage, there is good reason to expect that the appearance of this Grape would be much improved, its good quality being generally admitted.

—IN A LETTER received from Newbury, Canada West, dated December 16th, 1876, it is stated that Fahrenheit's thermometer has already registered 42° of frost—that is, 10° below zero; and on the above date, with a high wind drifting the snow about, the glass stood at 5° below zero. Last summer was intensely hot, and the Wheat crop which promised well

up to within a few days of ripening was attacked with rust, and the final result only came up to one-third of the average. Indian Corn was a heavy crop. Apples were most abundant, many of them having been sold at 10d. per bushel to be shipped to Great Britain. Trade is said to be very dull in that colony this winter.

— Owing to the protracted wet many BULBS, such as Hyacinths, Tulips, Crocuses, &c., which ought to have been planted in the autumn, are still in paper bags. If these bulbs have not grown too prominently they may still be planted, especially if covered with light soil such as decayed leaves or cocoa-nut fibre refuse. We have seen excellent beds of Hyacinths and Tulips from bulbs planted in January, but Crocuses planted at the same period have many of them decayed. The decay of bulbs is accelerated by making smooth holes for them with a blunted dibber—water traps. The bulbs should be planted in open drills in well loosened soil and be carefully covered with light material, so that the water can pass freely away. Bulbs planted now should not be covered so deeply as when planted in November; 1 or 1½ inch of light covering is sufficient at this period of the year.

DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

KITCHEN GARDEN.

THE weather is still so excessively wet that very little can be done to the quarters or borders in the way of digging or even wheeling the manure to them. We have continued pruning dwarf and standard trees, and also have proceeded with nailing the wall trees. Instructions for this work were given in recent numbers. Slugs have flourished amazingly owing to the wet and mildness of the weather. Frost and great depths of snow have been recorded from the north, but we have had no snow to speak of; it fell for a few hours a fortnight ago, but did not remain on the ground. The glass fell for a few nights below the freezing point, but not enough to arrest vegetation, and Roses and many flowering deciduous shrubs are hustling into buds. The most effectual way to destroy slugs amongst Lettuces, Cabbages, &c., is to dust the plants with quicklime by the aid of a lantern when the slugs are feeding. Dusting the leaves thickly does no harm to the plants. The lime may be applied a second or third time if the slugs are not destroyed.

Those who have to do with heavy clay soils which have been well drained will be sensible of the advantages of the draining; the ground will dry so much sooner after rains, and, if it has not been brought into good condition by trenching, this should be done at once. We have years ago seen the evil of trenching clay soils too deeply without taking care that the work was done gradually. For instance, say that a portion of good soil over a clay subsoil has been dug for many years to the depth of 10 inches, it would not be wise all at once to trench this to the depth of 20 inches or 2 feet; the pulverised soil on the top would then be the bottom 10 inches, and there would be 10 inches of unworked clay soil on the top, a bad medium in which to trust seeds or small plants in a wet season. Our plan with such soils is to work up a depth of 2 or 3 inches of the subsoil at each time of trenching until the required depth is attained. The vegetable refuse heap comes in useful for mixing with the subsoil, and if leaf soil is plentiful it is equally well adapted for the purpose. Stable manure is also much better adapted for such soils than that obtained from the cow or pig.

Pay strict attention to the beds of Lettuces out of doors, and see that decay and weeds are removed from them, and the ground is stirred with a Dutch hoe when the weather is sufficiently dry. Those plants under hand-lights, frames, or any of the numerous glass protectors should receive plenty of air, and the ground ought to be stirred with a pointed stick frequently. Cauliflower plants under glass require the same treatment.

FORCING HOUSES.

With the advent of the new year forcing of vegetables must be commenced in earnest. The Potato is easily forced, and is much esteemed early in the year. It may be grown on a hot-bed, or what is better in a heated pit. Only those sorts that have short haulm should be planted, and they ought to be freely ventilated after their growth has commenced. The pits and frames require to be fumigated occasionally to prevent the attacks of, or to destroy green fly. The Potato plants ought to be in a position where they receive the direct rays of the sun; a close moist atmosphere is not at all desirable for them. The best sorts are the true old Ashleaf Kidney if it can be obtained. There are many "improved" varieties, most of which are not so early, although they are prolific and have generally too much haulm. The Walnut-leaf Kidney is distinct from the above, and also well adapted for frame or pit culture.

Dwarf Kidney Beans when well grown afford a supply of most acceptable dishes. The Beans can be sown in any temper-

ature from 50° to 65°. In the higher temperature they come on more rapidly. What they require to produce abundantly is moderate pot room, a good rich loam, and being placed near the glass in a moist atmosphere. Some gardeners use pots as large as 12 and 15 inches in diameter, but such take up much room and are troublesome to move about; 7 and 8-inch pots are quite large enough with five or six plants in each. It is a good plan to sow thickly in a box, and when the seed leaves have grown to the full size to pot the plants, burying the stems in the soil up to the bottom leaves. It is necessary to syringe from the first to keep the plants free from red spider and thrips, and the pots should not be too close to each other. The blossoms must be exposed to light and air or they will not set well, and some of the pods will die off prematurely. A few sprays of Beech or Hornbeam should be placed in each pot to support the plants. Directly the pods are large enough they ought to be removed from the plants, whether they are required in the kitchen or not. A good plan is to tie them up in bundles of say fifty, and place each bundle in an upright position with the ends of the pods just covered with water; they keep best in a cellar. If the plants are supplied with manure water they will continue bearing for a long time.

Diets of early Peas may also be obtained by placing the plants on a shelf near the glass. They require more air and light than the Beans, and cannot stand such a high temperature; in other respects the treatment required is the same. A light or two over a hotbed may be used for a crop of French Forcing or Early Horn Carrots; a gentle heat from a bed of leaves is as good as anything. Six inches of soil about the place of the bed, and the seeds be sown in shallow drills. A sowing of the French Breakfast or Dwarf Turnip Radish may also be made on the same bed at the same time. The Radishes can be removed before they do any injury to the Carrots. Lettuce of the Paris White Cos type should also be sown under glass at this time, to produce an succession crop to that put out in the open ground or on a warm border facing south in the autumn.

Succession lots of Seakale and Rhubarb should be put into any place where the temperature ranges from 50° to 65°, instructions for which have been given so recently that no more need be added at this time. Some persons may not have the convenience of forcing houses or frames; such may have a supply of Seakale and Rhubarb by covering a portion over with fermenting material of some sort. It is necessary first to cover the crowns with pots 2 feet high, and about 15 inches in diameter, rounded at the top in the form of a bell-glass; a hole is made in the top, through which a lid is fitted, a bed of stable manure and leaves is then made around the pots, enough to cover them 6 inches deep. Excellent Rhubarb and Seakale is produced in that way, but it does not come on so fast, and the method is not so convenient as forcing the roots in houses.

Plenty of variety may be obtained in salads. Chicory may be had with the greatest ease. Eighteen roots may be potted in 10 or 12-inch pots, and the pots placed in forcing houses as they are required. Mustard and Cress will do anywhere if there is sufficient heat. The seeds ought to be scattered thickly on moist soil, and it is better not to cover the seeds, as the leaves that way are more free from grit, which is not easily washed from the salad. Mint, Tarragon, Parsley, and other herbs should be potted if they have not already been done, and they must be placed in heat according as there is likely to be a demand for them. The pots may either be forced upon hotbeds, or they may be placed in forcing houses where there is artificial heat.

Forcing Flowers.—A heated pit with a bed for plunging the plants in ought to be devoted to this purpose. A small house 20 or 30 feet long and 12 or 14 feet wide will produce a large quantity of flowering plants during the season, because as the flowers open they can be removed to the greenhouse and others be brought in to supply their place. Foremost on the list is the Rose. The last Rose of summer is a poor thing, although it may be found much later in the year than formerly; but the first Rose of spring is a treasure indeed. To be forced early the plants must be pruned early, and the buds will start strongly and well in a temperature of from 50° to 55°, and with a bottom heat of 85° or 90°. Water the roots moderately, and syringe overhead at least once a day with water rather warmer than the temperature of the house. Some of the most free-growing Hybrid Perpetuals and Teas are best adapted for forcing.

Hybrid Rhododendrons, which have now become so popular for shrubbery planting, may be forced with the greatest ease; but it is well not to place the pots in the plunging material, and it is not at all necessary that the plants should be near the glass, but may be relegated to the darkest part of the house. Let them be freely syringed and not suffer for the want of water at the roots, and in the same temperature as the Rose bushes they will soon come into flower. The plants may be lifted from the open border, potted at once, and forced almost immediately. Of course, only those well set with blossom buds should be chosen. When the first flowers open remove the plants to the greenhouse, where the remaining flowers can the

trusses will gradually expand, and they remain a long time in beauty. After flowering let the plants be gradually exposed to the open air, and in May they should be planted in the border from whence they were lifted.

Deutzia gracilis is a favourite plant, easily forced, and continues for a long time in beauty; its clusters of pure white flowers have a charming effect, and are a most distinct feature amid the dark foliage of *Rhododendrons* and the lively green leaves of the *Rose bushes*. Lilies, too, are most enjoyable, and who would be without a few small bushes now that they can be obtained at such a cheap rate ready for forcing? They are easily managed, and the above directions apply to them. Shelves near the glass may be fitted-up for *Hycacinths*, *Tulips*, *Polyanthuses*, *Narcissus*, and other Dutch bulbs. A few pots of *Diosytra spectabilis* ought also to find a place. Clumps of this when well grown form a very striking feature. The roots, as also those of the *Lily of the Valley*, are better with a little bottom heat.—J. DOUGLAS.

TRADE CATALOGUES RECEIVED.

Downie & Laird, 17, South Frederick Street, Edinburgh.—*Descriptive Catalogue of Vegetable, Flower, and Agricultural Seeds.*

John Jefferies & Sons, Market Place, Cirencester.—*Illustrated Garden Guide, and Catalogue of Vegetable and Flower Seeds, &c.*

Vilmorin, Andreux & Cie., 4, Quai de la Mézisserie, Paris.—*General Catalogue of Flower and Vegetable Seeds, Strawberry Plants, &c.*

H. & F. Sharpe, Wisbeach, Cambridgeshire.—*Wholesale Catalogue of Agricultural and Garden Seeds, and List of Seed Potatoes.*

Richard Bradley & Sons, Halsam, near Southwell, Notts.—*Abridged Catalogue of Roses and General Nursery Stock.*

James Wm. Mackey, 40, Westmoreland Street, Dublin.—*Illustrated Seed Catalogue and Amateur's Guide.*

TO CORRESPONDENTS.

All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

VIOLETS.—"D. W." inquires where *Violets odorata pendula*, *Biancayana*, *Reins Louise*, *Beauty of Louch*, and *Wilson* can be purchased. He has applied to several nurseries, but cannot procure any.

SULPHATE OF AMMONIA (Red Hill).—It dried it may contain 94 per cent. of ammonia, but if crystallized it contains about 92 per cent. It may be applied to any growing plant. Half an ounce to a gallon of water is sufficient.

ARBUCLAS.—"G. S." wishes for the direction of florists in the north of England who can supply *Arbutus*. If they advertised, our correspondent sends a brick bond and would soon see out any grower.

CORON FERT TREES (P. M.).—The distance of 30 yards will take five trees, the first trees to be 9 feet from the ends of the wire, and the three intermediate trees being 18 feet apart. They may be planted wider than that, but the trees will take so much longer to fill the space.

MANAGEMENT OF CAMELLIAS AND AZALEAS (Youthful Amateur).—We think you are rather impatient. If the *Camellia* buds do not drop they will swell out and open in 3 or 4 weeks. The distance of 30 yards will take five trees, the first trees to be 9 feet from the ends of the wire, and the three intermediate trees being 18 feet apart. They may be planted wider than that, but the trees will take so much longer to fill the space.

POINSETTIA PULCHERRIMA (Idem).—This plant blooms best in a temperature of from 50° to 55°; but will do with a lower minimum, say 55° for an average, a few degrees lower and higher than this according to the weather. The leaf enclosed seems to be from a species of *Funkia*.

MOULD ON ENCYCLAM CORNS (A. F. B.).—The mould will not injure the corns, as we apprehend it is a mossy covering consequent upon the plants having been kept very moist in an ill-ventilated atmosphere, the surface of the pots as well as the corns having the same green mouldy covering. Remove it from the surface of the soil with a piece of wool, and also from the corns if it comes away readily and may be done without injury to the skin, leaves, and flowers, which must not be damaged.

CHINESE PALMS FROM CUTTINGS (Idem).—Except for the double varieties propagation from cuttings is not nearly so good as raising plants from seed. The cuttings are best taken so soon as the winter is past, or from March to June, they requiring a rather close and warm atmosphere with shade to root freely.

OLD PLANTS OF CHRYSAANTHEMUS (Idem).—We should not keep the old plants only to give what cuttings were needed in March, and if none were required at that time we should throw the old plants away. We have fre-

quently directed the old plants after flowering, cutting away most of the old roots and potting in entirely fresh compost (all the old being shaken out) into 5 or 6-inch pots, keeping the plants in cold frames until April with abundances of air during mild weather, and shifting into larger pots then, and giving the flowering pots early in June. They did fairly, but the flowers were neither so large nor well formed as those afforded by plants from cuttings.

CARPET-BEDDING PLANTS FROM SEED (P. F. S.).—The *Coronaria*, *Cinoraria*, and *Mesembryanthemum* may be raised from seed, but are much better raised from cuttings. The seed may be sown thinly in pots of light soil, covering the seed very slightly and keeping the soil regularly moist, the pots being placed in a hotbed until the seedlings appear. After that a light and cool position must be afforded to harden the seedlings, which must, when large enough, be pricked-out in boxes or be potted singly in very small pots. *Colosseum* must be raised from cuttings. These and cuttings of all the plants mentioned will strike readily in sandy soil in your hotbed, affording moisture and shade to prevent the cuttings from flagging. We advise your procuring cuttings of the plants you require.

LILY OF THE VALLEY (Fifteen-years Subscriber).—The roots are not dead, but will grow and produce flowers in due time.

CLIMBERS DEFORMED (R. S. F. Gillingham).—Remove the decayed flowers, and, if possible, place the plants in a little more heat. They will improve as the season advances. The name of the plant is *Garrya elliptica*.

REMOVING TREES FROM A NURSERY (E. E. E.).—All trees, shrubs, and plants that you are a nurseryman, have planted in the nursery as stock-in-trade you can remove. If any of the trees have become too large for removal you must leave them uninjured, and cannot enforce payment for them from the landlord.

NAMES OF FRUITS (Bob).—Your Apple is *Court of Wick*. (J. J. S.).—The Pears were *unripe*, and we are sorry that we are unable to identify them.

NAMES OF PLANTS (Idem).—All forms of the purple variety *V. salicifolia*. (*A. Baderi*), *V. polydora villosa*; 2 and 3, *Lactuca scariola*; 4 and 5, *Scopolendium vulgare*. (*R. Matfield*).—*Leucodendron argenteum*.

POULTRY, BEE, AND PIGEON CHRONICLE.

POULTRY AND BIRD NEWS.

In the *Journal of Horticulture* for August 3rd last we described the result of a sitting of *Laghorn* eggs sent from Mr. G. Brown of Brookville, U.S.A., to Mr. Norwood of Salisbury. The eggs had hatched on June 23rd last, and several of the pullets from them laid when only five months old. We learn that the third-pipe pair of this breed at the late Show at Kingston-on-Thames came from this hatch. We observed them there because of their spotless purity of plumage and the colour of their legs, which were of a deeper orange hue than any we have before seen.

We know of one amateur who keeps two breeds of poultry, and those of kinds which most frequently have to go into a variety class. He has exhibited seventy-two pens in 1876 and won sixty-two honours. Of the ten other pens twice the judge missed them when making his awards. We consider this good work, and it shows us what an amateur can do. These birds have only been kept in enclosed runs in town gardens.

We wonder *Silkie*s are not more kept for useful purposes. They can always be depended upon for laying or being broody at this season. It is true they do not cover very many eggs, but they take every care of what they have, and rarely do one come to grief. We know of one exhibitor in the midland counties who has seven of these birds now sitting, and we have some broody hens ourselves waiting for eggs. The breed is to have a class at the coming Aquarium Show at Westminster, and as a certain number of entries had to be guaranteed we hope all will enter a pen who keep the variety, or the loss will fall upon private shoulders.

Torbis seem to be the present fashion in Toy Pigeons. Mr. Salter has lately sold a Black for £40. Mr. O. E. Cresswell has recently refused £20 for one of the same colour, and a Blue was sold at Birmingham we believe for £12.

It will be remembered that a few weeks back we recommended the fanciers of the various breeds to make themselves into clubs like the *Laghorn* fanciers had done. We hear the Spanish breeders have done this, and that one or two more such clubs are on the tapis. After this we shall want one large general club to embrace all these subdivisions, and so make, if possible, all fanciers members of one body without cliques or petty jealousies.

The Oxford Committee are already at work getting up cups and classes for the neglected breeds for another year's show. There will be, we hear, £10 10s. cups for Black Red cockerels and pullets, and a large sum of money has been offered to provide Langshan classes. We hope the Committee will refuse this offer, or suggest that the money should be expended in classes for *Pekin Ducks* or some other breed where there really is something worthy of encouragement.

We are glad to say the defaulting Committee of the Portsmouth Summer Show have been brought to book. The Hon. and Rev. F. Dutton placed the matter in the hands of his solicitor, who issued a summons for the amount owing. Not only has the prize money to be paid in full, but they have also the

second old birds. In Silver-spangles the great fault (which we find very prevalent in the north) was the bad combs of the cocks. Silver-pencils were good as regards the winners. *Dorkings* very good, especially the first, which were Silver Greys; and *Sprungs* were very good. In *Brahmas* the winners were mostly young, and in the *Polish* class most of the best were White-crested Blacks. *Bantams* had but one class, and in this Brown Reds were first, Black Reds second, and Blacks third; and in the Variety class were some good Houlans and Cochins.

Cage Birds were also good, a Belgian carrying off the champion prize; but there were some very neat Norwich and excellent Green Caucisies, also Cinnamon and Duts.

POULTRY—*Game*.—*Black-breasted and other Reds*.—Special, 1, and 2, T. Brown, 8, J. Rutherford, the W. Armstrong. Any other early—1, 2, and 3, H. Clarke, H. Beechington, J. Dickinson, and J. D. Washington. 2, J. Snowdon. *Golden-pencilled*.—1, E. Walton. 2, C. R. Senior. 3, J. I. Millcan, the W. White, J. I. Millcan, F. J. Snowdon. *Silver-spangled*.—Special and 1, J. I. Millcan. 2, J. JUDGE.—Mr. E. Hatton, Pudsey, Leeds.

THE PERISTERONIC AT THE CRYSTAL PALACE.

This Show is different to other shows, and the difference is for once of the pleasing kind, for differences are not always pleasing. "Other Pigeon shows," as one happily and neatly put it, "are competitive, this is comparative." No eager hasting with palpitating heart to the pens to see whether you have secured a prize, for prizes there are none; no agitation about the colour of the cards, for cards there are none; yea, not even a catalogue to get any over its bad arrangement, for catalogues there are none. Then, instead of little pens to bring down "the R's" wing, to the pen, and very late; and for a last instead, not a last looking frightened in a corner all by itself, or two making love or quarrelling, so like unfeathered bipeds, but a dozen or more in some cases, as in the *Almonds*, and the dear little *Black Mottles* a perfect carpet of soft-feathered beauty. 'Tis a friendly meeting of fanciers, so no fear, though it is held in the tropical department, that people will get hot. Old faces—*e.*, well known for some years, are around me; not old in another sense, for fanciers seem to me never to get old. I don't know one on two sticks, and if there be a fancier with one it is not for support, but only to pass carelessly over some pet *Ponters*' back.

No catalogue—no beginning to this Show. "Where shall I begin?" said I to a brother fancier. "Why, begin anywhere—here, pointing to the *Ponters*. Ah! he was a *Ponters* fancier, and so, deep dog, tries to get his class put first, and so for once he shall. *Ponters* not *Carriers* first. 'You *Ponters* are true to your name, for *Pont* you can, and no mistake, while *Carriers* can't carry."

Ponters.—Messrs. J. Gresham, Hill, Gill, and Hives sent specimens from their lofts. Mr. Gresham's birds being the row, and proud may be well be, particularly of a young *Black hen* in her teens; no, I mean in her months. A truly beautiful bird, which looks like a cock as to size. Legs very excellent, and particularly long in the shio. A very fine bird, would that he had been raven black. A very graceful young *Yellow hen* is another noteworthy bird of Mr. Gresham's, and a pair of very good coloured *Rods*. Capt. Hill sent some good birds from his stud, worthy of Castle Hill; the king of the castle being his old *Bine cock*, though lighter on the leg, and very tight in girth is his young *Blus*. Mr. Gill and Mr. Combe's birds followed, and were worthy.

Fantails.—Well, they are next, and no shall come next. Messrs. Maynard, Hemming, and Thurlkel were exhibitors. Those of the first-named were singularly beautiful, and in nestness, style, and elegance were supreme. Mr. Maynard's seems now to hit the man with English tail and Scotch grace, and motion.

Maggies only one pen—Mr. Herbert's.

Owls.—Messrs. Esquilant, Thomas, Stevenson, Jones, and Schwetzer sent birds. These were naturally from their owners, very worthy. Strange what a reaction has set-in in favour of English *Owls*, which but a few years since were to be annihilated; not that there were not some few exquisite *White Africans*, and a pair of *White with black tails* of Mr. Stevenson's. The exhibitors were Messrs. Combe, Hardy, Stephens, n. Thurlkel, Jones, Taylor, and South. Some few were the old-fashioned plain-headed. Mr. Hardy's were very fine; and Mr. Jones's, one especially of

his, a *Kite-barred Silver*, not a good colour indeed, but with a beautiful head. Good in face were some also of Mr. South's; while certainly some of our exhibitors' birds were overlaid. Two such of Mr. Stevenson's were excellent in colour, it being a sound *Yellow*.

Jacks were very numerous. Messrs. Combe, Hardy, Maynard, Royde, Jones, Betty, Bird, Heritage, and Eadsen, sent from their lofts. I admired much Mr. Betty's *Yellows*; he seems particularly lucky with that colour in Pigeons. Their chains of great width, the mass well up, and the chain coming well forward. Much ground seems now to be gained in this class, as colour, mane, chain, but narrowness of shoulder and forwardness of head are still to be won. Whites are advancing, though most as yet in points behind the others.

Barbs.—Messrs. Chandler, Maynard, Jones, Hedley, and Heritage showed specimens. Mr. Hedley's capital *Black* and *Rods*, Mr. Jones's *Reds* and *Yellow*, while Mr. Maynard was prominent with a pen of young *Blacks*.

Antwipers.—Messrs. Cocksey, Flecker, Chandler, Theobald, and Tegetmeier sent some of these useful birds; while Mr. Hudson, who, as one said, must have as many birds as the King of Oude himself, sent large pen after large pen of *Homers*. One pen of very uniform *Silvers* of his I greatly admired, also a pen of *Bine Chequers*, the right *Chequer* after all.

Pigmies were from the lofts of Messrs. Tegetmeier and Hives. The latter-named gentleman also exhibited some very laudable whole-coloured *Jacobins*. The points were not over-good, but the change in colour pleasing, while the bloom was like a black drake's. Mr. Hives had also those *Malay-like Pigeons*—*Scandarrons*, richly coloured uglies.

Sally late in my account must now come the *Carriers*—from fifteen different lofts, their names known to all fanciers. Magnificent birds were shown by Col. Hassard, Messrs. Crisp, Hedley, Ord, and others. Perhaps those to notice especially are the Whites. The Colonel had a *White bird* there of great excellence, no *Dragon*, but a *Carrier*. So also another fancier, Mr. Hodgson I think, and Mr. Crisp. Now, I do trust that when a class for *White Carriers* is offered it will be filled, not by big *Dragoons* or *Horsemen*, but by the genuine birds. This I must chronicle as the advance in respect of *Carriers*.

Dragoons were hardly so numerous as usual of late. Messrs. Thomas, Keeler, Betty, Whitehead, Sargeant, and Tegetmeier sent fine specimens. Mr. Sargeant's *Yellows* were very attractive.

I have reserved the *Short faces* for last. Little genes indeed. Their exhibitors were Messrs. Hemming, Ford, Merce, South, Murphy, Newman, Jayne, and Taylor. Some pens were empty. If the young of *Almonds* of various shades, from the light colour of the young to the dark of the old; some excelling in head and beak, others birds of colour. Interspersed with showy *Agates*, and one pen (would there had been more of the prettiest of the pretty) *Black Mottles*, Mr. Hemming's. Mr. Ford's *Almonds* were worthy of so good a breeder, and Mr. Jayne's. Mr. South had two pens, one of *Balds*, the other of *Black Beards*. The *Short-face* part was, I noticed, much crowded and much criticised.

As a whole this Show was a very pleasing and good one. We were asked not to look at jaded over-shown birds, but birds fresh from lofts, often lofts of those who never show for competition; hence the result was pens of neat, trim, healthy birds. The Society does the fancy credit and itself honour by such an exhibition. It is also a hospitable Society, for a lunch was provided, where one chatted agreeably with old friends and made new acquaintances.—WILTSHIRE RECTOR.

THE BATTLE OF THE HIVES.

Which is the best hive? is an old subject of controversy—as old as the hills. In this Journal, as elsewhere, this question has often led to many a keen discussion, but it is one which is not confined to this country alone. In America especially the "battle of the hives" has raged with far greater fury than here, so that among the numerous patented "best hives" brought out there, and they are legion, the most recently invented is usually announced to the confiding public as the superlative of all.

While admitting that there are many aspects or phases of this question which might be very properly and profitably discussed either as regards definite or general objects, yet the simple question itself, "Which is the best hive?" has always appeared to me a very foolish one. Certainly I could not wish all my experience presume to answer it, and I could not wish any intelligent sparian better able than myself. If such a question were asked of me, I could only reply after the Irish fashion of questioning my questioner, with the view of ascertaining what is meant by "best."

In the controversy presently being carried on in these pages, entitled "Hives," "Moveable versus Fixed Combs" &c., notwithstanding a great deal of extraneous and irrelevant matter introduced in regard to the facilities and uses of moveable frame hives and the assumed connection of the straw skep with the

sulphur pit, I think I can discover that the old and, as I thought, exploded idea—that to the kind of hive we are indebted for large honey results—still haunts the minds of some of our apiarian brethren, and that therefore the real question raised in this controversy, and which is at the root of it all, is simply this, "Which is the best hive for producing most honey?" Assuming, then, that I am right in this view of the discussion, let us see how the matter really stands.

On the one side we have your indefatigable correspondent Mr. Pettigrew, the staunch advocate of the large straw skep with its fixity of combs, and on the other side Mr. Briscoe and your old and excellent correspondent "A RENFREWISHRE BEE-KEEPER" in support of the bar-frames or Stewarton hive, each claiming for their respective favourites the advantages of producing the largest honey yields. Now, I have gone over all the communications of these gentlemen with the greatest care, and I have failed to notice a single particle of evidence adduced either that the straw hive, in virtue of its being straw, has any advantages over the Stewarton, or *vice versa*, the Stewarton, in virtue of its being a Stewarton, over the straw hive in producing the alleged honey results.

Mr. Pettigrew has, it is true, shown that both in his own apiary as well as in others immense stores have been collected by bees domiciled in straw hives, and this, no doubt, with the object of proving that they are the best honey-producing hives; but while he does this, why does he acknowledge to feel "staggered" in his faith in the "straw" in reading the report of the Renfrew success? In the Stewarton, unless he begins to doubt at first of both either the one domicile or the other, apart from system, has anything to do with results so far as weight of stores is concerned?

"A RENFREWISHRE BEE-KEEPER," however, has seemingly more faith in his Stewarton than Mr. Pettigrew in his "straw." All doubts on his part seem to be dispelled, if indeed they ever existed. After referring to unfair comparisons, the one hive with the other, in different localities, he triumphantly asks, "If a straw skep yields 96 lbs. in South Devon, what would a Stewarton colony there give?" and we have then a narrative of "facts" from his own apiary in evidence of the Stewarton's superiority over the straw hive. According to this narrative there stood in his garden two colonies, one located in a roomy straw skep and the other in Stewarton boxes. Both were presented with queens of the same age, and each had an overflowing population. Being thus treated equally matching, both were treated according to the same system, all depriving hives, and so with the view of testing their relative merits as honey-producers. The result was that the Stewarton yielded 68 lbs. in super honey, the straw about 21 lbs., while the former had amassed large stores in the boxes below, but the straw skep, relieved of its super, required feeding.

Now, I rather think that no intelligent apiarian can accept this narrative of facts as a test or evidence of the superiority of the Stewarton over the straw hive at all. The same results might occur even if the competing hives were both Stewarton. Similar differences take place in every apiary, and that too betwixt hives apparently working under equally favourable circumstances. In not a few cases we could determine the cause, and, considering the impoverished state of the stock straw hive referred to after removal of the super, there is some ground for suspecting that all was not right with that colony. If "A RENFREWISHRE BEE-KEEPER" thinks the reverse, he will kindly state how the results are to be otherwise accounted for. Is it by reason of the form, material, or construction of the Stewarton hive which enabled it to eclipse so greatly the straw skep in the amassing of stores? or what is it? "A RENFREWISHRE BEE-KEEPER" so far explains his views in one of his communications by comparing the old straw skep to the "antiquated rasping hook," and his favourite hive to an "improved implement or Stewarton hive;" but I doubt how far apiarians generally will concur with him in this illustration. Most of us, I presume, look upon the hives, not as the "raspers," but simply as the storerooms in which the bees, the real rasps, amass their sweets.

The "bottle of the hives," in this aspect of it, is not a new affair. We have had the question more than once discussed in these pages, but it ever and anon crops up anew after a brief repose, and though always set at rest for the time, yet, like the Phoenix in its ashes, it again rises up with renewed fury; but I have no doubt that the good sense and intelligence of all concerned will occur, as before, in coming to the conclusion that no such adventitious circumstances as the kind of hive alluded to can have much or any influence on the amount of stores collected by the bees.

Before concluding these few remarks, I cannot help joining with Mr. Pettigrew in protesting against the idea of straw hives being in any way whatever allied to the brimstone pit, nor can I sympathise with any of the depreciatory remarks regarding its general uses as a bee domicile easily managed by our cottagers. Apart from such advantages which our observatory, frame, and Huber hives afford for experimenting, and studying the internal

economy of the hive and the natural history of its wonderful inmates, we do not look upon the modern straw skep with dis-favour. It has some redeeming points of excellence as a bee domicile in our cold northern climate. It is cheaply made and can be easily managed, and many of the ordinary operations of modern bee-keeping can be managed as safely and as well with straw skeps as with moveable frame hives.—J. J. LOVIE.

OUR LETTER BOX.

FOWLS WEAKLY (Mrs. W.).—Feed your fowls well, give them good oats twice per day, and any rough cooked meat you may have chopped-up small. If you have no ground oats give them barley.

LICHTIAN BEES (Mrs. Wray).—Write to any of those who advertise in our Journal.

METEOROLOGICAL OBSERVATIONS.

REMARKS.

- 3rd.—Showery all day, and wet evening.
 - 4th.—Very wet morning, showery dull day; fine evening, but wet night.
 - 5th.—Fair early, bright forenoon, cloudy by 1 P.M.; showery all the remainder of the day, and windy at night.
 - 6th.—Dull and damp all day, and windy at night.
 - 7th.—Raining at 9 A.M., but fair soon after to midday; rain in afternoon, and at times heavy.
 - 8th.—Very dull, dark, rainy day, at times unusually dark.
 - 9th.—Dull morning with showers; but fine afternoon.
- Temperature very similar to previous week, and rainfall excessive. The yearfall at this station being on the average about 23 inches, it is evident that the fall in each week (25-53) may be expected to be about half an inch. The fall in the last nine weeks has been as follows:—Week ending
- | | | | | | |
|-----------|------------|--------------|-----------|------------|--------------|
| Nov. 14th | total rain | 1.246 inches | Dec. 19th | total rain | 0.791 inches |
| " 21st | " | 1.863 " | " 26th | " | 2.679 " |
| " 28th | " | 0.992 " | Jan. 2nd | " | 1.255 " |
| Dec. 5th | " | 1.673 " | " 9th | " | 2.017 " |
| " 12th | " | 0.683 " | | | |

Giving a total in nine weeks of 12.671 inches, or exactly half the usual fall in a twelve-month—that is to say, we have had six months' rain in the last nine weeks.—G. J. SYMONS.

COVENT GARDEN MARKET.—JANUARY 10.

ALL kinds of early forced vegetables—such as Asparagus, New Potatoes, Rhubarb, and French Beans—are now putting in an appearance, and in consequence of slack trade are realising low prices. Peas are restricted to Easter Benri; and No Plus Meuris, while Apples are nearly off the market.

From observations taken near London during forty-three years, the average day temperature of the week is 42.8°; and its night temperature 31.6°.

CLIMBING ROSES.

ALTHOUGH not a modern rosarian, I do not consider the Journal quite complete if it does not contain something about Roses. I do not take their omission quite so much to heart as the "WYLD SAVAGE" does, who regards it a very "black Thursday" if his favourites are not mentioned. I do not look upon the Rose with the same eyes as that "child of nature." He looks for each individual bloom being perfect in itself, paying little attention to the tree producing it, so long as that tree is vigorous and capable of perfecting his ideal blooms for cutting and placing in the front ranks of the aristocracy of Roses—if indeed there is such a position in a family admitted to be regal. I look at the trees more than the blooms—Roses in the garden rather than Roses in the exhibition tent. He takes pleasure in cultivating those varieties which require skill to produce them in perfection, and the greater the difficulties he encounters the greater is his satisfaction when having overcome them. Those Roses are the most dear to him which have cost him the most labour. I take pleasure in other Roses—those which are regardless of deep soil, rich manure, the season's fullness, and the pruner's dexterity.

My favourite Roses are those which will flourish without turfy loam or roadside trimmings, and which are proof against serious injury from the nibblings of a few stray sheep. My favourite Roses are those which require no liquid manure, no disbudding, no protection from cold, no shelter from wet, no shading from heat. My Roses thrive in any kind of soil—in clay, or sand, or gravel, or chalk: on any aspect, from the south side of a cottage to the north side of a church—on the keen exposure of the bleak hillside, or in the bowery shade of woodland walks; Roses, in fact, which grow without my care—(I am afraid I am an idle rosarian)—the old-fashioned climbing Roses.

My ideal Rose tree is the old Boursault Rose AMADIS. What a tree that is! not a tender shrub, but a real tree planted at the north side of a villa, and which has grown in wild luxuriance far above the eaves, covering every part of the roof and even embracing the chimneys. When that tree is in its summer dress studded with thousands of blooms the Roses of the garden in their prim proud dignity are dolls in comparison. This real Rose tree is never watered, never pruned, never nailed, and never fails to produce its annual harvest of crimson trusses.

I have other Roses which I admire—which all admire who see them. They drape the walls of a village church, adding beauty to that structure. These Roses are literally "churchyard blossoms," making "God's acre" cheerful, as it should be, by their purity and sweetness. The south side of the edifice is not too hot for them nor the north side too cold. They have bloomed there for many years, even from the days of my childhood until now. They are secured to the walls with iron staples, and are pruned annually with the garden shears, and under this rude treatment they flourish such as no other Roses—no other

climbers of equal beauty could flourish. They are the old, old climbers.

There is the flesh-tinted Alice Gray; the purely white, densely double, wondrously free, Bennett's Seedling or Thoresbyana. There is the light pink of Dundee Rambler; the bright rose, with glossy foliage, of Adelaide Orleans; the bright red and bright red of Gracilis and Fulgens; the charming, in its smallness, its fulness, and its purity, of Felicite Perpetue; and the light crimson and deep crimson of Elegans and Amadis. These are the Roses on my parish church which have lived so long and bloomed so well; so constant are they and so enduring that they seem as if they would never wear out, but appear to whisper the words of Tennyson on the rolling river—

"Men may come and men may go,
But I go on for ever."

Assuredly many have come and gone since these Roses commenced blooming, and in all probability many more will "come and go" before these old-fashioned parochial Roses "belong to the past." No other Roses could exist so long under the same conditions. With my own hands I planted (I was not an idle rosarian then) other and more modern Roses amongst them—not modern now perhaps, yet good—Charles Duval, William Jesse, Chénelode, Lord Raglan, Brennus, Pierre de St. Cyr, La Ville de Bruxelles, Général Jacqueminot, Coupe d'Hebe, Gloire de Dijon; but all are gone except "the Gloire" on the north side and Coupe d'Hebe on the south—both of them beautiful I admit, yet not equal in exuberant beauty to the old-fashioned climbers.

These old-fashioned climbers are also to be seen and admired in other forms and in other places. Being parochial Roses they were, and are, regarded as public property; but that claim has never been abused—indeed, putting it on no higher grounds, there has been no reason for abusing it, for cuttings have been freely given to all who have desired them, and now these old and homely Roses adorn many a humble dwelling, as well as impart a charm—a powerful one—to at least one "great garden" where all the modern Roses are cultivated and cherished. These old climbers are everybody's Roses, and flourish anywhere. They clothe the walls and fences in all aspects and all exposures; they drape long poles and form "pillars of beauty"; they cover banks and knolls, and hang in wild luxuriance over crags and rocks; they form great bold groups in shrubberies—thickets of flowers powerfully attractive from their massive grace and rambling freedom, and they make bright and sweet the shady twisting walks of wilderness scenery—half garden half wood. What other Roses can grow and bloom like these? No others can. Then for gathering in huge armfuls, hamperfuls, vanfuls for festival time—a birthday fête, a society's anniversary, a harvest home—what other Roses can be more acceptable, more admired than these? None can. For these reasons the old-fashioned climbers are my favourite Roses, and I would not that they should be forgotten or their merits ignored. I do not expect them to be recognised by the Rose Society, I do not want them

to be; they are not society Roses, but garden Roses—Roses of and for home, and not for arranging in formal rows in some great city hall or gigantic marquee.

I have not enumerated all the Roses which are suitable for this free and enjoyable mode of adornment, but only a few which are immediately under my notice. There are others of these old climbers which are possibly worthy of mention, and which are doubtless admired in many places, where they form great natural wreaths over some rustic fence, some old wall, some precipitous bank, or some venerable edifice. It is in such places where they are most "at home," where they flourish in their own semi-wild beauty—their charming simple gracefulness. Are there not places some such as these in most villages and in many gardens? then cover them with these old-fashioned climbing Roses.—A PARSON'S GARDENER.

MRS. PINCE'S BLACK MUSCAT GRAPE.

"A GRAND Grape when well grown" is a very general remark made in reference to this variety. The experience which has been recently recorded in the Journal teaches that cool treatment or, in other words, a short season of growth, is not sufficient for the requirements of Mrs. Pince's Muscat. That it has been "well grown" under what is termed "cool treatment" is certain; so has Muscat of Alexandria by Mr. Taylor at Long-leat, also by other growers in other places. But cool treatment, it should be remembered, must not be connected with late starting of the Vines, or the season of light and a genial temperature becomes unduly limited. It is not only not unusual but very common to retard the starting of late Grape Vines to the utmost possible moment—firstly, because of the preservation of the late-hanging fruit, and secondly because of the erroneous, but as yet not quite exploded, notion that late starting and late ripening are essentials to long keeping.

When Mrs. Pince's and other Muscats finish well when grown under "cool treatment" it is generally when the Vines have been started early, and kept steadily growing under a moderate artificial temperature throughout a long period of light. Mrs. Pince's Muscat I have found to ripen perfectly under that treatment, but I have not found it to do so when started late and grown as coolly as possible through a necessarily short season. Evidence has recently been afforded that this Grape has been improved by growing it in a higher temperature than had previously been the case, affording it a longer period of growth. My experience quite coincides with that of other cultivators on the advantages resulting from this change of treatment.

Having noticed that Mrs. Pince's Muscat ripened well with a low temperature I grafted it on a Black Hamburgh Vine in a house in which Vines were grown, principally for the purpose of affording shade for Ferns, Orchids, &c., after the bedding plants had been removed from the house at the end of April or early in May. For the sake of the bedding plants the house was kept as cool as possible, and the growth of the Vines was retarded to the utmost, and they were afterwards grown without the assistance of fire heat. In this house Black Hamburghs ripened perfectly, but Mrs. Pince was far from being perfect. The Grapes were fairly good in flavour, but their appearance was almost repulsive from their greenish-brown skins. The Vine was continued in the same house for four years, but during that time did not perfect one really satisfactory bunch of Grapes. It had what it was said to require, "cool treatment," but it was wrong treatment. I referred to the early reports of this Grape, which were generally so favourable, and here I found, what many persons besides myself had forgotten, that the Grapes first exhibited in such fine condition had been grown under what was termed a "cool treatment," but the Vines had been "started early with the assistance of a little fire heat." Many remembered only the "cool" part of the conditions, having overlooked "early starting" and the "little fire heat" assistance—forgetting, in fact, by far the most important part of the question.

By way of following more exactly the mode of culture originally described as successful I trained my unsatisfactory Vines through the glass division and into the next compartment, where the Vines were started in February. This house was also managed on the "cool treatment" system—that is, the fruit was set at a minimum temperature of 50°, and 60° was never exceeded by fire heat alone. The principle of management adopted was for the fire to do as little as possible, and the sun as much as the Vines could endure. It was still "cool treatment" according to the general acceptance of the term,

but was sufficient for Mrs. Pince's Muscat, which now produced Grapes more highly esteemed by their owner than any other variety. The Grapes which the same Vine formerly produced of a reddish-brown colour now became black, especially on those laterals which were not overcropped and which carried a large proportion of foliage, say four to six leaves beyond the bunch.

I had written thus far when the Journal arrived, and where I note that further testimony is given of the importance of affording Mrs. Pince more heat and a longer period of growth than has been customary. I am satisfied that if this plan is carried out (of course in conjunction with good and well-managed borders) less complaints will be heard of the failure of what I believe to be one of the best late black Grapes in cultivation, for Mrs. Pince is undoubtedly a "grand Grape when well grown."—A RETIRED GARDENER.

SELECTIONS OF SEEDS.

I NAME only those kinds that are always reliable, and so far as I know the best, taking quality and quantity into consideration.

Peas.—Early: *William I., and a few days later Alpha. *Dwarfs*: Bine Peter and Unique. *General crop*: *Dr. Maclean, G. F. Wilson, and *Culverwell's Prolific Marrow. *Late*: *Premier, Ne Plus Ultra, and as a dwarf *Omega. *Broad Beans*.—Early Longpod, *Seville Longpod for early; Monarch Longpod and *Windsor Improved for main crop. *Dwarf Kidney Beans*.—For early and forcing Osborn's New Forcing; and main crop, *Canadian Wonder and Negro Longpod. *Running Beans*.—*Scarlet Champion. Mont d'Or Butter Beans are by some very much esteemed.

Broccoli.—*Dwarf Green Curled and Cottagers' Kale. *Broccoli*.—*Winter: Snow's Winter, preceded by *Veitch's Self-Protecting Autumn. *Spring*: Veitch's Spring White, Culling's Matchless, *Leamington. *Late*: *Lander's Goeben and Sutton's Perfection. It is presumed that Broccoli (Cauliflower) are demanded from November to June. *Brussels Sprouts*.—*Strymer's Giant. *Cabbage*.—*Hill's Dwarf Incomparable, *Wheeler's Cocoa-nut, Nonpareil Improved, and Wheeler's Imperial. Red Dutch for pickling. *Savoy*.—*Drumhead, Dwarf Green Curled. *Spinach*.—Round for summer, prickly for winter. *Cauliflower*.—Early: Dwarf Erfurt Mammoth. *General*: *Walcheren. This is usually classed as a Broccoli, but how is unintelligible.

Celery.—*Leicester Red (Major Clarke's Solid Red), Williams' Matchless Red, *Sандрingham Dwarf White, Williams' Matchless White. *Chicory*.—*Large-rooted, not that I can see inferior to Witloof, and like it (if there is any difference) occasionally having the "blanched" leaves splashed with brown like a spotted Cos Lettuce. Very desirable for winter salads. *Corn Salad*.—Broad-leaved Italian sown in August is a good addition to salads in autumn, winter, and spring. *Cress*.—Curled. *Mustard*.—White. *Endive*.—*Batavian Improved Round-leaved and Green Curled. *Lettuce*.—*Cabbage*, for summer: *All the Year Round and Neapolitan. For autumn sowing to stand winter: Stanstead Park. For frames: Early Paris Market, All the Year Round, and Commodore Nutt. *Cos*: Alexandra (a selected Paris White), *Hick's Hardy White. For autumn sowing: Brown Sugar-loaf (Bath), *Brown (Bath), black-seeded. For frames: Hick's Hardy White and Brown Sugarloaf.

Cucumber.—Duke of Edinburgh (Munro's), first-rate for frames; Tender and True, and *Telegraph. *Out-door*: Stockwood Ridge. *Melon*.—*Read's Scarlet-flesh. *Green-flesh*: *Easton Castle and Meredith's Hybrid Cashmers. *White-flesh*: *Cox's Golden Gem and Queen Emma.

Onion.—*Reading, White Spanish or Portugal, Danvers Yellow, Brown Globe, and *James's Keeping. For drawing young: White Lisbon. For pickling: Silver-skinned. For autumn sowing: Giant Rocca. *Leks*.—*Carentan and Mueselburgh. *Beet*.—*Dewar's Dwarf Red and Pine Apple Short-top. *Carrot*.—For forcing and warm border for early: French Forcing. For summer: Early Horn. Winter: *Red Surrey and James's Intermediate. *Turnip*.—*Early Snowball, White Stone or Six-weeks, the last with *Golden Ball for winter. *Parsnip*.—*Hollow-crowned Improved. *Radish*.—*French Breakfast, Scarlet Short-top. For winter: China Rose. For forcing: French Breakfast and Wood's Frame. *Rampion*.—A desirable winter accompaniment of salad; used like Radish. *Salsify* and *Scorzonera* both have roots that make a desirable dish.

Seakale for raising plants for forcing, to which I will again revert. *Asparagus*.—Conover's Colossal.

Tomato.—"Orangefield Dwarf, Hathaway's Excelsior; if a yellow be wanted Green Gage.

Vegetable Marrow.—Custard, *Long White.

In herbs are new Fern-leaved Parsley, Sweet Basil, Sweet Marjoram, Summer Savory, Anise, Angelica (a biennial), Borage, Caraway (biennial), Coriander, Dill, Pot Marigold, Purslane (green and golden), and others, continued solely by seed. Many may be raised from seed of the perennial class. I treat Sage and Thyme as biennials, sowing in spring, having plenty of green for cutting by autumn, and cut entirely for drying the following year and destroy.

Potatoes.—Early and for forcing: *Veitch's Improved Ash-leaf. *Second early*: Lapstone, or its improved form Yorkshire Hero, Rector of Woodstock. *Main crop*: *Snowflake, Walker's Early or *Prince Regent. *Rhubarb*.—*Johnson's St. Martin's, the finest forcing and early kind; *Monarch, a very large green kind, and late.

Those distinguished by a star are considered most desirable, and are intended to express the limit of kinds for general purposes.—G. ABBEY.

THE NEW ROSES OF 1876.

The Lyons Rose-growers, who send out annually novelties in Roses, announce this autumn the sale of many which have already obtained certificates of merit.

We shall commence with the gains of M. Antoine Levet of Route d'Heyrienx, Montplaisir, Lyons.

Mlle. Lazarine Poizeau, Tea.—Plant vigorous, very free-flowering. Flower medium size, full, fine form and handsome, and of a beautiful orange-yellow colour. This beautiful Rose was awarded a first prize at the special exhibition of Roses at Lyons in the month of June last. The same grower also sends out the following:—

Mme. Sophie Tropot, H.P.—Plant vigorous, almost without spines. Flower large, full, fine form like the old Cabbage Rose, and of a beautiful bright rose colour. Very effective.

Mme. Gabriel Fournier, H.P.—Plant vigorous, with straight branches. Flower very large, full, of fine form and dark rose colour. This beautiful plant of the highest merit has obtained a first prize at the exhibition of Roses at Lyons in June last.

Souvenir de Paul Dupuy.—Plant very vigorous. Flower very large, 6 inches in diameter, very full and of good form, dark velvety red. This, though not a Hybrid Perpetual, will take its place among the most beautiful varieties of hybrid Roses.

From the establishment of Madame Ducher of Lyons the following three Roses will make their appearance:—

Souvenir de George Sand, Tea.—Plant very vigorous, with short branches. Flower very large, full, of very fine form like that of a Tulip, yellow tinged with salmon; the reverse of the petals banded with lilac.

Triomphe de Milan, Tea.—Plant vigorous; branches short and straight. Flower large, full, of fine form, white with a deep yellow centre. This is a very beautiful and fine variety.

The stock of the beautiful Tea Rose *Mme. Welche*, named after the wife of the Prefect of Lyons, and which obtained a first prize in the month of June at the Rose exhibition at Lyons, has been sold to Mr. Henry Bennett of Salisbury, England. The sale of it will deprive us, no doubt, for some time of the pleasure of having this beautiful Rose in the nurseries of our French rosarians.

M. Ph. Rambeaux, Rue Neuve Charpenne, Lyons, informs us that he will send out the following two new Roses:—

M. Druet, H.P.—Tree very vigorous and very re-blooming, with elegant foliage. The flower of this Rose, raised from Duchesse de Cambacres, is of a globular form, recalling the colour of the old Cabbage Rose, with a very decided carmine centre.

Madame Pawort.—This is a new variety of the Bengal race, very vigorous, and very re-blooming. The flowers are very large, elegant, and very full, white with a pale rose centre.

The Horticultural Association of Lyons nominated at its sitting of the 15th October last a special committee, composed of Messrs. Bernaix, L. Charlin, and Guillet fils, to examine on the spot and to give its appreciation of a seedling Rose obtained by M. Joseph Schwartz, rosarian of Repas, Lyons. This new Rose, named *Comtesse Riza du Parc*, belongs to the section of *Tess*. Its branches are erect and branching. The young foliage is at first purple, then passes to a brilliant green. The buds are long, on stout footstalks. The flower is solitary, large, globular, full, of the colour of the China Rose with a coppery yellow ground. The plant is very vigorous,

very re-blooming, and flowers abundantly. This was raised from the *Tea Comtesse de la Barthe*.

The conclusion of the committee with regard to this new Rose is, that it is a plant of the first order, and one of the most beautiful obtained in the *Tea* section, meriting a prize of the highest class.

A beautiful new Rose has been obtained by M. Liabard which bears the name of *Emma Hall*. It was awarded a prize at the Lyons exhibition, and is in form like *La France*, with a beautiful deep rose colour. The plant has a fine habit, and it is said is very beautiful.

At present we know of but two new Roses obtained by the rosarians of Brie, and they will not be sent out till next May as grafted plants by M. Cochet, the rosarian of Snines. The first, which is a seedling from the beautiful Rose Charles Margottin, is a very vigorous plant with very straight branches and magnificent foliage. The flower, of good form, is very large, full, very deep red, and the reflex petals bright salmon. This beautiful new Rose, which we have seen and appreciated in the nurseries of the raiser, will bear the name of *Madame Bonnier*. The second, which will be sent out at the same time under the name of *Madame Roher*, is a magnificent plant raised from *Triomphe de l'Exposition*, extremely vigorous and very free-flowering. The flower is large, full, of good form, and its colour is of a beautiful bright rose with pale silvery reflex. This Rose was awarded a first prize at the Exhibition at Brie-Comte-Robert in the month of July last by a jury composed of Messrs. Levesque, Eugene Verdier, Hippolyte Jamin, &c.—(*Journal des Roses*.)

(To be continued.)

PLANTING EARLY POTATOES.

WHILE it is pleasant to see "A YOUNG AMATEUR" taking an interest in this important eculeut, and disposed also to give information as to its better cultivation, it is not desirable that erroneous teaching should be passed in silence.

The unsound portion of the advice on p. 33 is that suggesting the desirability of planting early kidney Potatoes 6 inches deep in January, instead of permitting the tubers to make some growth in a light place out of the ground preparatory to planting them.

I can conceive a position where kidney Potatoes, without having pushed their eyes, might be planted 6 inches deep in January—namely, in a bed of leaf soil at the front of a south wall. There they might grow, and possibly produce a crop; but in ordinary open positions, and in ordinary soil, and that "ordinary" being, as it so often is, more or less close and heavy, the probability is that not more than 50 per cent. of the sets would grow at all. Strong-growing round Potatoes would grow under that treatment, but the more tender early kidney would, many of them certainly, refuse to do so. Should the season prove very cold and wet failure must follow that mode of planting, and even under the influence of favourable weather the crop would not be more than half a success. I write on this subject after much experience, many trials, many failures, and some successes in Potato cultivation; and I would firmly impress on all never to plant early kidney Potatoes, and especially early in the season and deep in the ground, before the tubers have made some growth out of the ground.

Early planting is not productive of early produce. So convinced am I of that, that I should not hesitate, were I residing near a "A YOUNG AMATEUR," to enter into a mutual arrangement with him to this effect. We should both take our sets of early kidney Potatoes from the same stock. He should plant his share 6 inches deep on the first day of January, the sets then showing no signs of growth; and I would plant mine three months afterwards (the first day of April) on the same plot of ground, and I should confidently expect that my crop would be ready for digging before his, and also be more productive; in other words, my sets would grow more effectually out of the ground than his would in it. My reason for arriving at this conclusion is that I have tried the experiment repeatedly, and in every instance the results have been in favour of having encouraged a healthy growth of the sets before they were planted.

But while I should not hesitate to enter into a friendly competition under the conditions named, it does not follow that I in all cases advocate planting so late as April. I attach no importance to a mere date for the sowing or planting of any crop, and especially early Potatoes. A week sooner or later is of trifling import compared with the state of the

weather, the character of the ground, the condition of the sets, and the locality.

I am particularly acquainted with one garden where the best crops of early Potatoes are produced by planting well-prepared sets early in March, or even the last week in February if the weather is specially favourable. The soil of that garden is as light almost as leaf soil, and the rainfall of the locality is extremely slight. When placed in the ground thus early the sets have made growth (sprouts) at the least half an inch in length, robust, green, and studded with rootlets. So firmly are the sprouts affixed to the tubers that they may be turned out of one basket into another in the most careless anyhow manner, and not one sprout will be knocked off. That is the condition in which "seed" Potatoes should be at planting time. When planting early in light soil the sets are covered quite 4 inches deep. The object is to induce roots being formed some distance below the surface of the ground, and beyond the reach of the sun's rays, which throughout May and early June are generally so powerful as to seriously arrest the growth of the early Potatoes in this light and dry soil.

That is the practice the best suited for one garden, and now for the other. The gardens are not far apart, and both of them have been under my charge for several years. No. 1 (mentioned) is light and dry, No. 2 heavy and wet. Early and deep planting, which is the best for No. 1, is entirely unsuited to No. 2. In this garden the very last days of March or early in April, according to the state of the soil and the weather, is amply soon enough for planting. One of the best and earliest crops I ever had in this garden was from sets planted on April 12th. These tubers had each made growth an inch and more in length and proportionately stout; each "sprout" was studded with rootlets and was crowned with a cluster of leaflets. These were only just covered with soil, or say to the depth of a quarter to half an inch. They appeared above the surface just in time to escape the spring frosts, grew without check, and one of the finest crops of early Potatoes I ever reaped in was cleared off the ground on June 24th. A few similarly planted on the same date in the light soil of No. 1 garden did not produce nearly such a good crop, and some planted early and deep in the cold, strong, wet soil of No. 2 garden did not come up at all.

Such are the teachings of experience. The deductions derivable therefrom, the soundness of which have been proved by many and careful experiments, are, that careful preparation of the sets, by encouraging their robust growth in a light place, is imperative; that in light soil and dry districts early and rather deep planting is advisable; that in heavy soil and wet localities late and shallow planting is the most profitable, and that the state of the soil is of more importance in deciding the time for planting than the date of the calendar. I have given the practice best suited for two extreme cases, and no one need have any difficulty in "shaping his course" on the date given, determining his position and acting accordingly; but never—let me say it emphatically—never plant early kidney Potatoes 6 inches deep in January in cold, heavy, wet soil before the tubers show signs of growth.

A word may be added on the mode of planting. The soil, be it remembered, cannot be too clean and friable for this crop. It should be manured and dug deeply in the autumn, leaving it in ridges if it is at all of a heavy nature. When these ridges work down freely in the spring level them, and after the surface is again dry, dusty if possible, planting may be done. The ground should be again forked over, planting the Potatoes at the same time, the rows being not less than 2 feet apart. The drill or channel next the line should be made broad and level and of the proper depth for the sets. After these have been placed in the row it is excellent practice and highly worth the little trouble it entails to sprinkle over and around them the following compost in a dry state:—Wood ashes and old vegetable refuse in equal parts, to every two barrowfuls adding an 8-inch potful of superphosphate of lime, the same amount of soot, and half the quantity of salt. This spread half an inch (less or more) in the drills will greatly improve the value of the crop. In cold heavy soils the salt may be omitted. In such soils, and especially where the Potatoes do not turn out cleanly, it is first-rate practice to cover the sets (using also the ashes, &c.) with old, broken, half-decayed straw—old thatch answers admirably—previous to placing the soil over them. It is surprising how beneficial this is both in increasing the bulk of the crop and in contributing to the brightness and cleanliness of the tubers. The early Potato crop—the south-border crop, is so important as to be worthy of a little extra

care, and I know of no assistance that can be given more effectually in increasing the quantity and improving the quality of the produce than that of applying the side I have recommended at the time of planting the tubers. It is by the adoption of some such practice as is here detailed that prizes are won.

Let me conclude with a warning to young enthusiasts who intend "going in" in preparing the sets. I was an enthusiast once, and went in strong on the preparing point. Even that excellent practice can be carried too far, as I found to my cost. My early Potatoes, taken up at the end of June, were at once spread out thinly—preparing. The summer was long and hot. By the autumn they had made growth fully large enough for planting. They were continued in the light throughout the winter, and in March some of the "sprouts" were nearly as large as the parent tubers to which they clung—large, hard, barrel-shaped protuberances, each having a tuft of green leaves. I was extremely proud of them, but my pride sustained a fall. I planted them with extra care in the full consciousness of being rewarded with an extra crop, but—that terrible "but"—not one of them grew. Each gigantic sprout was transformed into a tuber, and was surrounded with a pealike progeny, while not a vestige of green appeared above ground. My employer had taken great interest in my pet tubers, and during the process of preparation I had represented to him (perhaps a little pompously) that I was "assisting Nature." When the failure was established he made me a present of the following remark:—"You have either assisted Nature to make a fool of herself, or she has made a fool of you." I have never felt comfortable when dwelling on that remark; and need I say that, except for the purpose of experiment, I have never since prepared my "seed" Potatoes so violently, so extremely? That failure taught me that extremes are dangerous, that moderation is the safe guide, that intelligence is necessary in all gardening matters, even in preparing Potatoes.—A NORTHERN GARDENER.

THE LADIES' DESIDERATUM WATERING-CAN.

The annexed can enables ladies to water the upper shelves in their greenhouses without the danger of upsetting flower-pots by having to step on the staging.

When it is required to fill the can with water it is lifted out of the wire frame into which it is hooked, and which frame is mounted on a stiff rod or bamboo some 4 or 5 feet long. The can thus being raised to the desired spot is tilted by means of the string.

This can may be obtained through the Rev. T. W. Huthwaite, Backwell, Bristol, by whom it was invented and patented.

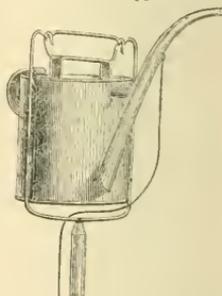

Fig. 5.

ROYAL HORTICULTURAL SOCIETY.

I HAVE received from a well-known amateur horticulturist of good position in Yorkshire some comments on my own and on Mr. Abbey's letter in the same number of the Journal, which perhaps you may like to have. "One more scrawl in the midst of my busy life to urge you to stick to your plan. I do not yet follow you on some secondary points, but in the main you are obviously right. Like me, and my father before me, hundreds of amateurs have hitherto ignored the Royal Horticultural Society, as we should ignore any other fashionable lounge society. Let those who enjoy pay. But offer to make me for a small sum Fellows, full members, or what you please to call us (but call us all alike) of a working scientific society, and we will gladly subscribe, though nineteen out of twenty of us will get nothing personally for our money. It will be regarded by us as an subscription for the promotion of horticulture.

"Mr. Abbey's schedule of payment are far too elaborate, and therefore too indefinite. I did think of the two classes—town members, £3 3s.; country members, £1 1s. But your plan seems best. And do not use clear of fashion; remove all temptation of this kind. I have sent out all the circulars you sent me, and will send more if you will let me have them. P.S.—I

am strongly with Mr. Abbey in desiring to affiliate country societies. [Hear, hear.—G. F. W.] I would make an associate class at 5s. per annum, or 10s. *hd.*, of working gardeners or working-class amateurs."—GEORGE F. WILSON.

ROYAL HORTICULTURAL SOCIETY.

JANUARY 17TH.

THESE useful meetings appear to increase in popularity, and this, the first gathering of the year, was highly successful both as regards the character of the exhibits and the attendance of horticulturists. The tables of the Council-room were nearly filled with plants, and there were also some dishes of noteworthy fruit, especially a Pine Apple from Mr. Miles of High Wycombe—the identical fruit that was exhibited before the Committee on December 6th, 1876; so that altogether quite an attractive exhibition was provided.

FRUIT COMMITTEE.—Henry Webb, Esq., V.P., in the chair. Messrs. Lott & Hart, White Hill Nursery, Faversham, sent a seedling Apple for kitchen use, called Hart's Glory; but the Committee were of opinion that it did not possess merit superior to many other varieties in cultivation. Mr. Fowler, The Gardens, Harewood, sent fruit of the Charlesworth Tokay Grape from the old Vine at Harewood, which this year has ripened upwards of three hundred bunches. The flavour was delicious, and a letter of thanks was awarded to Mr. Fowler. Mr. Miles, The Gardens, Wycombe Abbey, exhibited bunches of new fruit of Black Hamburgh, being the second crop from the same Vine within twelve months. The colour was excellent, and the Grapes had a fine fresh flavour. A cultural commendation was awarded to Mr. Miles. Mr. Miles also exhibited a fruit of the same Pine which he submitted to the meeting seven weeks ago. Although it was not so sound as the former fruit, still, considering the period of seven weeks since it was cut, it was in excellent condition and of fine flavour. Its condition assured the Committee that it is one of the best, if not the best, keeping winter Pines; that it was named Lord Carrington and was awarded a first-class certificate. Dishes of *Heurde de Jonghe* and *Joséphine de Malines* Pears were sent from the garden at Chiswick. The former was in fine condition and of excellent flavour.

Mr. J. Hepper, gardener to C. O. Ledward, Esq., The Elms, Acton, exhibited three boxes of fine Mushrooms, to which a cultural commendation was awarded.

The death of Mr. Alfred Smece, F.R.S., who was for some years a member of this Committee, and whose great scientific knowledge was frequently of much service, was reported to the Committee, and a letter of condolence was agreed upon to be sent to Mrs. Smece and family expressive of the great loss which they and science had sustained by Mr. Smece's death.

FLORAL COMMITTEE.—W. B. Kellock, Esq., in the chair. Sir Trevor Lawrence, Bart., M.P., Burford Lodge, Dorking, had a first-class certificate for *Lælia Dayii*, an intensely rich and beautiful flower with carmine sepals, a rich purple maroon lip and striped throat; second-class certificate for *Dendrobium Lindleyanum*, pinkish white sepals and yellow lip; and a botanical certificate for *Schlimia trifida*, an Orchid with a leaf resembling that of a Stanhopea, and white, bell-shaped, wax-like flowers of great substance and delicately perfumed. This distinct and remarkable plant was closely examined and much admired by many visitors. Excellent groups of plants were exhibited by Messrs. James Veitch & Sons, Royal Exotic Nursery, Chelsea; Mr. B. S. Williams, Victoria Nurseries, Holloway; Messrs. Charles Lee & Son, Royal Vineyard Nursery, Hammer-smith; and Mr. Ollerhead, gardener to Sir Henry W. Peck, Bart., M.P., Wimbledon House.

Messrs. Veitch's collection of plants was composed of Orchideæ—medium-sized plants extremely well flowered of Cattleya Trianae, very gorgeous; a great display of *Lycaste Skinnerii*, *Odontoglossum Alexandræ*, *O. Andersonii*, *O. triumphans*, *O. Rossi major*, *O. pulchellum*, *O. Hallii*, and the strikingly spotted *O. cirrhosum*. There were also *Cypripediums* *Sedeni*, *veixillarum*, *villosum*, *venustum* *parvium*; *Sophrontes grandiflora*, *Pleione humilis*, *Lælia albidia* and *anceps*; *Masdevallia polysetica* and *ignea*, and *Cologyne cristata*. Messrs. Veitch also staged excellent *Cyclamen*, superior pots of Lily of the Valley, a span of the intensely brilliant *Aphelandra aurantiaca* *Roezlii*, the pure and sweet *Toxicoplia spectabilis*, and a group of hybrid *Amaryllidæ*. A silver-gilt Davis medal was recommended to be given for this collection.

Mr. Williams's group comprised ornamental-foliaged plants, Palms, *Dracæas*, &c., well-berried *Solanums*, and highly attractive *Orchidæ*, including *Cypripedium* *insigne*, *C. venustum*, *C. Harrisonianum*, and the beautiful *C. Dayanum*—a splendid plant in splendid condition—*Odontoglossums* *luteo-purpureum*, *Pectostori*, *cordatum*, *Alexandræ*, &c.; *Zygopetalum crinitum*, *Masdevallia*, *Lælia*, and *Goodyera discolor*. Mr. Williams also staged half a dozen plants of *Primula sinensis* Queen of Whites, the flowers being very pure, of great substance, well fringed,

and exceeding 2 inches in diameter. A bronze Davis medal was recommended to be given for this group.

Messrs. Lee's collection, which was very extensive, comprised many choice *Conifers*, *Cupressus*, *Retinosporas*, and *Junipers*; also *Ligustrums*, *Enonymæes*, *Hollies*, and a large and varied assortment of stove and greenhouse decorative plants, and a vote of thanks was deservedly awarded.

Sir Henry Peck's collection was attractively arranged, and the plants were in excellent condition. The groundwork was formed of the following *Orchids* were springing in charming contrast:—*Calanthe Veitchii*, *Lycaste Skinnerii*, *Odontoglossum pulchellum*, *O. Bietonenæ*, *O. Alexandræ*, *O. Roezlii*, *Cypripedium niveum*, *C. insigne*, *C. venustum*, *C. Sedeni*, *Oncidium cheiroporum*, *O. Weltoni*, *Cattleya Trianae*, *Phalaenopsis grandiflora*, *Cymbidium ensifolium* (sweet-scented), *Saccolabium violaceum*, *Lælia anceps*, *L. albidia*, and *Cologyne cristata*. Mr. Ollerhead also exhibited in a separate group *Todea superba*, *Coccos Weddelliana*, and *Crotoms*. A bronze Davis medal was recommended for the collection.

A large and excellent collection of dried Ferns and leaves was exhibited by Mr. Howard, nurseryman, Balham Hill, for which a silver Davis medal was recommended to be given. The colours of the leaves had been exceedingly well preserved, and the Ferns were almost as fresh-looking as if growing, although some of them had been cut in 1875.

Mr. Dean, Ranelagh Road, Ealing, exhibited a collection of *Victoria Regina* and *Neapolitan* Violets, also seedling *Primroses*, and a vote of thanks was awarded.

From the Society's gardens came flowering sprays of *Chimonanthus grandiflorus*, the *Glastonbury Thorn*, *Lonicera Standishii*, and *L. fragrantissima*.

SOIL FOR VINE BORDERS.

We recently noticed the superior nature of some Vine shoots which had been sent to us by Mr. Wipf, gardener to N. Clayton, Esq., Lincoln. That wood was correctly described as being nearly as hard as oak, and almost destitute of pith. The following is in reply to an inquiry as to the nature of the soil which had assisted in producing that wood, and is one more proof of what may be done in successful Vine culture with good management and proper additions to ordinary soil, without the much-coveted rich turfy loam:—

"The greater portion of the soil was taken from the site of the Vine border—a black adhesive compound destitute of fibre, lying on the limestone; the rest of the soil I procured from the neighbourhood, which was of a light sandy nature. I coveted what is termed strong loam, but such could not be procured except from a long distance and at prodigious cost. I therefore made the best I could out of materials on hand, and mixed freely with the soil bones, charcoal, wood ashes, and a little manure. I elevated the border 2 feet above the ground level in spite of light soil and little rainfall, trusting to an unlimited water supply. Twice during the season I mulched the border with some strong slaughter-house manure, which prevented the border from being parched-up, but at the same time warming the soil above the ground level to a mild hotbed temperature. Evening was chosen for watering the border, the water then being much warmer from having been in the pipes all day, the latter laying very close to the surface of the ground. The roots have travelled 5 feet into the outer border, and are within a few inches of the surface; no manure water was applied. The subsoil of the borders was of a loose rubble limestone formation. I had it all taken out to the depth of 2 feet and passed through a coarse riddle (3 inches); the stones were then replaced, the largest at the bottom and the smaller on the others evenly levelled down. Below that rubble there lies a loose limestone bed to the depth of 8 to 10 feet, terminating below with a bed of ironstone full of clefts and crevices, therefore ample and efficient drainage for 10 feet of rain per annum is secured. Inside treatment as to moisture and ventilation was carefully attended to, a little air having always been left on both day and night.—ALBERT WIPF."

NOTES AND GLEANINGS.

THE Mr. Sage referred to by Mr. Luckhurst in his appeal of last week is Mr. THOMAS SAGE, who died on the 23rd nit. at Hammersmith at the early age of thirty-three years. He commenced his gardening experience under Mr. Dornay in the nurseries of the Messrs. Veitch at Exeter, and subsequently was foreman at Gopnal Hall (Earl Howe's) and at Gunners-bury (Baron Rothschild's), eventually becoming gardener to

Sir Edward Dering, Bart., at Surrenden, and when there was an active member of the Committee of the Ashford Horticultural Society. Mr. Sage was an earnest and successful gardener and a worthy man.

At the meeting of the ROYAL HORTICULTURAL SOCIETY held yesterday, Lord Alfred S. Cholchill announced that the next meetings of the Fruit and Floral Committees, on the 14th February, will be held in the conservatory, and that a military band will perform during the afternoon.

The South-Eastern Railway Company conveyed on the 10th inst. from London *via* Folkestone and Boulogne, *en route* for Milan, 948 cases of SILKWORKS' EGGS, weighing 26 tons 11 cwt. This consignment was from Japan.

The *Germantown Telegraph* has published the following relative to the value of SALT AND SOOT AS MANURES:—Mr. Cartwright received from the Board of Agriculture the honorary reward of a gold medal for a valuable set of experiments made by him to ascertain the value of salt in agriculture. Of the soil he used nearly three-fourths was sand, the remainder consisted of calcareous and vegetable matter, with alumina and a small quantity of oxide of iron. Having tried all the usual manures alone and differently combined, he found of mixed manures that salt and soot were superior to all others. The produce upon which these experiments were made was Potatoes, and it was observed that wherever salt was used this root was free from scabiness, with which it is commonly infected. One peck of soot and a quarter of a peck of salt were used to a bed 1 yard wide and 40 yards long." Our correspondent, "A NORTHERN GARDENER," in another column speaks highly of the value of salt and soot as manures for Potatoes, and we know him to be an experienced and successful cultivator.

ALTHOUGH the COMMON HOLLY has not produced many berries in the last year, the variegated-leaved varieties have been prolific, and a correspondent, Mr. J. Hardie, reports the same observation from Scotland.

PUBLIC attention is almost constantly being directed to the advisability of planting TREES in TOWNS, and every week the matter is discussed by parochial boards and vestries. On every consideration the planting of trees in such places is desirable, and experience has taught that the best of all trees for the purpose are Planes. Other kinds of trees will exist in smoky places, but not flourish with the same vigour as Planes. A point in favour of these trees, and which weighs heavily with continental authorities, is that Planes retain their foliage until late in the autumn, and then cast it all at once immediately after the first smart frost, and thus the interminal litter caused by the falling of the leaves of other trees over a long period, and the consequent and frequent sweepings necessary for cleanliness, is avoided. Planes, in short, are the healthiest, the handsomest, and the cleanest of all "town trees." In parks and suburban gardens other trees thrive more or less satisfactorily, Limes, Elms, Chestnuts, Thorns, Acacias, Laburnums, and the Tree of Heaven (*Ailantus glandulosus*), but for avenues in streets no trees are comparable to Planes.

ALLOTMENT GARDENS FOR THE POOR.—Mr. J. Wright writes to the *Times* from Springwell, Saffron Walden:—"In a parish in which I was born, and which formed a part of the large estate of the late Lord Maynard in Essex, his lordship required his tenants to allow every cottager to occupy from 10 to 40 poles of land near to his dwelling, and at the same rent per acre as that paid by the farmers; and many years back, and during his lordship's life, I heard blessings invoked upon him for having filled the belly of many a poor man's child which otherwise would have gone empty; and, as the same system is continued by the trustees of this estate, I should be glad to see the labourers, by the work of their hands, raise some lasting memorial to the memory of so benevolent a nobleman. In the parish of Willesden, in which I have resided for the last thirty-five years, I established the present system of allotment gardens, of which there are now about sixty, and in the summer months anyone may see in Pound Lane, in a field granted by Mr. Prout of Neasden, the working of the system, and the highly-prized productions of the tenants. I have lived to see the fallacy of Mr. Malthus's arguments, for there is no redundancy of population; but, on the contrary, every able-bodied man can find employment at considerably increased wages, and the Union houses are no longer needed, and ought not to exist except as asylums for the aged and hospitals for the afflicted."

WE regret to hear of the death, at the age of 53, of Mr. ALFRED SREE, F.R.S., which occurred on Thursday at his residence, 7, Finsbury-circus. Mr. Sree was born in the City, where his father was chief cashier in the Bank of England, and he had resided in the City all his days. He received his early professional education at the Aldersgate School of Medicine, became a member of the Royal College of Surgeons in 1840, and a Fellow in 1855. He held the office of surgeon to the Bank of England, being the first appointed. Mr. Sree was well known for his practical knowledge of electricity, and had given his name to a galvanic battery, being besides the author of many practical works connected with electricity and professional subjects. He was the inventor of the present mode of printing Bank of England notes. His best known works are: "Electro-Metallurgy," "Sources of Physical Science," "The Potato Plant; its Uses and Properties," "Principles of the Human Mind," "Instinct and Reason," "Lectures on Electro-Metallurgy" delivered at the Bank of England, and "The Process of Thought Adapted to Words and Languages." One of his latest works was "My Garden," in which he minutely describes his garden at Croydon. Mr. Sree was a director of the Gresham Life Office, the Protector and Accident Assurance Companies, and the East London Railway, an active member of several institutions, and he was for many years a member of the Scientific and Fruit Committees of the Royal Horticultural Society. He was also for seven years a Member of Council of the Society. The annual flower shows in the City have lost in him an enlightened supporter.

FASCIAED BRANCHES.—In reference to a broadly flattened branch of a Sweet Potato, Mr. Meehan, at the Philadelphia Academy of Sciences, said these branches were found on numerous plants, and there was no reason why all plants may not be found to produce them. They were species of fasciations which took different forms at times. In trees they often appear as "crow's nests." The old theory referred them to over-luxuriance; but in a paper published in the *Troy Proceedings of the American Association* it was shown to be just the reverse. In union there is strength, in vegetable as in other bodies. Any tendency to a multiplicity of small shoots on a tree instead of making a few large branches, all other things being equal, is an evidence of lower vitality. And this was proved by these fasciations. In severe winters fasciated branches were the first to die; often they were the only branches that were destroyed. Again, it had been shown in his papers before the American Association and before the Academy of Natural Sciences of Philadelphia, that only when a flowering portion of a plant was in the best conditions to maintain its hold on life, in other words in the highest conditions of vitality, did it produce pistils or female flowers. With a lowered or depreciated vitality the male organs of the flower or male conditions were favoured, and it was a singular fact that whenever these fasciations flowered, the female organs were nearly always abortive, and stamens and petals increased at their expense. These were some of the facts which had proved the old notion that over-luxuriance in the sense of high vital power had nothing to do with fasciations, but rather the reverse. This was as near to the full explanation as science could get as yet.

In the month of July last says, the "Journal des Roses," M. Paul Brunaud of Saintes (Charente Inferieure), presented to a meeting of the Central Horticultural Society of France the description of a remarkable monstrosity of the Provins Rose. This Rose is prolific, and the shoot which proceeds from the centre of the flower has, one following the other, two other flowers more or less rudimentary, above which is a small cluster of leaves. Its calyx is developed into normal leaves, of which four have five leaflets and the fifth three. This is one of the freaks of nature which are sometimes met with where Roses are grown to any great extent.

CYTISUS RACEMOSUS OUT OF DOORS.

This useful plant is generally found growing in pots in greenhouses, and is considered a great acquisition to the conservatory at this season of the year. To me it is a novelty to see this useful greenhouse plant grown to perfection in the open air. We have several specimens growing here, two of which have stood unprotected since the year 1869, and have grown to the height of 6 feet and measure 12 feet round. They are now blooming freely and are likely to continue so for a long time. Those plants are quite hardy and always bloom twice a-year. In April the old wood that has flowered is removed

with the clipping shears, the plants then start into rapid growth and flower again in July. My reason for writing about the *Cytisus racemosus* is that its hardiness is not generally known. Any person seeing it in bloom and healthy as it is here cannot fail to say it well deserves a prominent place in every shrubbery.—A. CAMPBELL, *The Gardens, Muckross Abbey, Killarney.*

NATIONAL ROSE SOCIETY.

THE lovers of the queen of flowers will be glad to hear that matters are progressing satisfactorily with regard to the new Society founded in her honour. An informal meeting of the Committee, at least of those members resident in and near London, has been held at the Horticultural Club, holding the same relationship to the general meeting of the Committee that the "pourparlers" at Constantinople did to the more important meetings now being held—i.e., plans were brought forward to be submitted to the general meeting of the Committee which will be held on the first Wednesday in February. Amongst other important matters a schedule for the first Show of the Society on July 4th was prepared to be submitted to the members of the Committee, so that when they meet they will have had time to digest it and make suggestions for alterations and improvements, when it will be printed and circulated. I may state that the prizes suggested are very liberal, and amount in the aggregate to upwards of £230, and that this will be for cut Roses alone. No pot Roses or vases of flowers, or any miscellaneous subjects, are recommended. It was also suggested that each member of the Society should have two admissions for the Exhibition to admit them an hour before the general public. To all real lovers of the Rose this will be a real boon, as it will give them an opportunity of quietly looking over the stands exhibited.

It was also proposed that in the various localities where the Rose is in favour someone should be requested to act as local Secretary, for the purpose of advancing the interests of the Society, securing members, &c. Several well-known amateurs have already signified their readiness to act in this capacity, and I have no doubt that I shall shortly be able to announce a goodly number who have thus consented to act. So far, then, all is working well; and although the time of year is unfavourable and the season depressing, yet I have every confidence that the work so auspiciously begun will be effectively carried out.

I should add that it is one wish of the Committee when they publish their schedule to announce on it the date of the various Rose shows throughout the kingdom, and if possible to prevent that clashing of interests which has been found so detrimental; and communications are now being opened with the Secretaries of the various societies to ask their kind aid in this matter.—D., *Deal.*

BERRIED SOLANUMS FOR WINTER DECORATION.

Few plants are more easily grown and at the same time more useful for the winter decoration of the greenhouse than the above. I will detail my practice in growing them, which has hitherto given very satisfactory results.

If the object is to have good plants in small pots I find it best to sow the seed about the middle of November in gentle heat. The young seedlings will be ready to prick-off in thumb pots the first week in January. In six or eight weeks they will require a shift into 4-inch pots, still keeping them in a warm pit or frame. By the end of April or early in May they should have another shift into pots a size or two larger. This with me is their final one. At the end of May, or when all danger of late frost is over, I plunge them in ashes out of doors where they are sheltered from high winds but fully exposed to the sun. When they fill their pots with roots they should have frequent waterings with manure water, and should remain plunged till they have set and swelled-off their fruit, which will be about the middle or end of September. I find the November sowing always gives more satisfactory results than spring sowing. With regard to older and larger plants I cut them well back in April, and at the end of May prepare a bed of free rich soil about 12 inches deep on a hard bottom. The plants are then turned out of their pots and the old balls considerably reduced, and planted out about 2 feet apart each way. They are taken up and potted in as small pots as possible towards the end of September. It is a good plan to cut

round the balls with a spade or edging-cutter two or three weeks previous to this. After potting keeping them in a close frame, shaded from hot sun and syringed overhead once or twice a-day for a fortnight, they will then bear free exposure to air and light. The berries will speedily change colour, and in the dull months of winter amply repay the little trouble and attention required to grow them.—J. E.

[The sprays sent (*Solanum capsicastrum*) were loaded with highly-coloured berries and strikingly handsome. We never before saw any so densely fruited.—Eus.]

VENN'S BLACK MUSCAT AND DUKE OF BUCLEUCH GRAPES.

It is somewhat surprising to find Venn's Muscat Grape so condemned by Mr. Wildemith and spoken so highly of by other good growers. What can be learned by these conflicting statements? Does the situation suit Mr. Wildemith's Vine, or in what way can the early shrivelling be accounted for? I have fruited Venn's Black Muscat two seasons, and find its produce a grand Grape of easy cultivation. We had it ripe in July, and kept a specimen bunch till November quite fresh and plump and of delicious flavour. I do not remember anyone recommending it as a late Grape, but for an early or midseason Grape of easy cultivation nothing can surpass it. It is a good grower, profuse bearer, free setter, ripening as early as a Black Hamburg, with a rich Muscat flavour.

The Duke of Buccleuch has fruited here two seasons, and has proved very satisfactory under precisely the same treatment as the above—that is to say, the Vines have had no special treatment or coddling whatever. The Duke of Buccleuch is a little earlier than Venn's Muscat, and the fruit may not keep so long; however, we kept a bunch two months in fine condition, and showed it at the Dundee International Exhibition, where it was much admired.

I should advise "ASPIRING AMATEUR" to give these Vines a fair trial, and if he has room to plant Black Hamburg and Foster's White Seedling as supernumeraries.—J. H. GOODACRE, *Elvaston.*

FLORISTS' FLOWERS IN THE SOUTH.

THE harp of "D." of Deal, as illustrated in his retrospect in your last week's issue, seems yet to be "upon the willows," and somewhat out of tune. He says he has "been twitted for saying florists' flowers are at a discount in the south," but whilst he "cheerfully acknowledges the attempts that are being made to revive an interest in them he is compelled to abide by his view."

Will you permit me to say, that instead of seeing in the work going forward attempts to revive an interest in florists' flowers, I look upon that work as an incontrovertible proof of the vital living interest existing in them? and I assert that logically no other interpretation is possible. Further, "D., *Deal*," tell us he has "been accused of disloyalty to the cause for having said this," and adds, "to all who know the deep and hearty interest I have taken in florists' flowers all my life this will seem simply an absurdity."

Well, I know something of this deep and hearty interest of which "D., *Deal*," speaks, and I ask you to allow me to propound to him the following question:—Has not this deep and hearty interest in the case of the Auricula, his favourite flower, brought him in reference to its classification, mode of showing, and properties into antagonism with the late Rev. George Jeans and the Rev. J. Bramhall—in Roses with Messrs. Rivers and William Paul—and in Carnations and Picoetes with Mr. Dodwell? The names quoted are those of gentlemen of weight and authority in connection with the flowers named; and I shall but record the simple fact, that in the conflict of opinion in each case, "D." of Deal won no followers, but remained, as he seems yet perversely resolved to remain, the sole exponent of his very singular and paradoxical views.—Z.

ARAUCARIA IMBRICATA CONING.

IN No. 824, page 27, a correspondent says, "Can you inform me if it is usual for the above tree to bear seed to perfection in this country?" On reading the above I thought it might not be uninteresting to say that this ornamental and truly beautiful tree coned freely in 1873 in the rectory gardens of the Rev. Henry Bourchier Wrey, Tawstock, North Devon. Not having seen Mr. Wrey's trees since that date, I cannot answer

for their coning sines. As far as I recollect there are three of these trees planted in a triangular form on a slightly elevated mound which have coned and ripened seeds for several successive years previous to the date above mentioned. I believe Mr. Wrey has raised several plants from the seed. In 1874 the reverend gentleman gave seeds to many of his friends and acquaintances, with directions for their successful growth.

—J. COLE McARDELL.

SOME SPECIES OF PRIMULA.—No. 3.

FOREMOST among the genera, companions of my early days—genera now neglected—I place Primula. Where now can the species *amena*, *verticillata*, *Pallasii*, *villosa*, *farinosa*, *nivalis*, *marginata*, and others be found in England? There are a score of species, many of them formerly cultivated in our gardens, yet how rarely now do we meet with any but varieties of the Primrose, *Polyanthus*, and *Auricula*.

We have published notes on two species, and we purpose affording similar justices to a few more.

PRIMULA VILLOSA, OR MOUNTAIN PRIMULA.—Mr. Curtis, in the first volume of "The Botanical Magazine," published in 1787, says, "This plant has been introduced pretty generally into the nursery gardens in the neighbourhood of London within these few years. Mr. Salisbury informs me that a variety with white flowers, brought originally from the Alps of Switzerland, has for many years been cultivated in a garden in Yorkshire.

"It is not noticed by Linnaeus. Professor Jacquin, in his "Flora Austrica," has figured and described a *Primula*, which, though not agreeing so minutely as could be wished with the one we have figured, is nevertheless considered by some of the first botanists in this country as the same species. He gives it the name of *villosa*, which we adopt, though with us it is so slightly villous as scarcely to deserve that epithet.

"It varies in the brilliancy of its colour, flowers in April, and will succeed with the method of culture recommended for the round-leaved *Cyclamen*."

The leaves are fleshy, slightly hairy, rhomboid, toothed on both sides towards the end. Scape an inch long, bearing one or two flowers; these are purple, segments heart-shaped, eye pale. Calyx not mealy, hairy, bell-shaped, half the length of the tube.

It is a native of the Swiss and Carinthian Mountains.

KEEPING LATE GRAPES.

ARE your correspondents, who in previous numbers attribute the cracking of the berries of Grapes to excess of moisture at the roots and to a deficiency of foliage to appropriate the excess of moisture, correct in their assumptions? I think not entirely. I have not time at present to enter fully into the

subject, but it may suffice for all practical purposes to illustrate what I mean by one or two instances of my experience in keeping late Grapes. When with Mr. Brunless of Argyle Lodge, Wimbledon, he suggested as a means for preventing the cracking of the berries the thinning-out of the lateral branchlets, and by degrees the whole of the wood of the current year's growth nearly close to the bunches. I acted on the suggestion and found the fruit keep in excellent order, and have practised the same thinning-out by degrees of superfluous wood and foliage ever since. The Grapes this year are keeping first-rate, notwithstanding the borders are saturated with wet. We have Black Hamburgs perfect in outline of bunch still; in fact, as many as will see us into February.

The only Grapes which have not kept satisfactorily this season were some Black Hamburgs ripened in August in a span-roof house and planted in the pit inside the house. The roof is nearly decayed, and the rain kept a continual state of dampness in the house in October and November, so that we were glad to cut the fruit. Strange to say, on giving the border a winter dressing lately it was found in a rather dry state, so that moisture in excess at the roots could not militate against good keeping in this instance.

I think "A NORTHERN GARDENER" hits the real cause of the mischief. Until a few weeks back—in fact, till the foliage was all but entirely off the vines, as there are still a few leaves hanging, we kept as nearly as possible a temperature of 50° and never attempted to dry up moisture on fine days, as there is as much harm done this way as any other. A temperature of 45° is the lowest I like to see the glasses registering now. What with the requirements of a family to supply during winter and spring, and a large flower garden to stock in summer, we require all our glass for storing and growing plants as well as fruit, so that the Grapes here do not receive what might be termed the best accommodation. No kind of fruit will keep well when the temperature fluctuates much, nor when there are extremes of dryness and moisture, and Grapes do not require much moisture in the atmosphere to induce their decay.—R. P. B.

Fig. 6.—PRIMULA VILLOSA.

BARHAM COURT.

THE SEAT OF ROGER LEIGH, Esq.

THERE are several places in England named Barham, the name signifying in modern English a fenced residence—that is, a house in an enclosure. The word Court added means that it was the enclosed residence of the feudal lord. Anciently it was spelled Bereham, but this had a similar signification, for *Ber* is the Saxon for a hedge. Barham Court is a manor, and in the time of Henry II. had for its lord the Archbishop of Canterbury, of whom it was held by Sir Randal Fitzurse, one of the assassins of Archbishop Becket in 1170. He fled, and one of his relations took possession of the manor and assumed from it the name of Berham. It remained in the possession

of the family until the reign of James I., when it was alienated to the Rev. Charles Fotherby, Archdeacon of Canterbury, from one of whose descendants it passed to Sir Edward Dering by marriage. It was afterwards the seat of Lord Kingsdown, and now belongs to Roger Leigh, Esq.

Barham Court is thus an "old place." Its mansion is old and plain, its trees ancient and gigantic. It is also a "new place." Former proprietors have done their part in the picturesque planting of "ancestral trees," and the present owner has done his part in making a modern garden.

Few places in its district are more worthy of a "gardening visit" during the summer season than this. The drive from Maidstone to Barham is a pleasant drive of four miles. It is through a district of Cherry orchards and Hop plantations, which on the left-hand side of the road are conspicuous over a great extent of landscape. On the right-hand side the ground is higher, and on one of the highest parts of the ridge

Barham Court is situated. The view from the front of the mansion is commanding and beautiful, embracing a wide-stretching undulating vale of great fertility and well wooded. The mansion is not "embowered in trees" obstructing the view, but the trees have been judiciously planted or thinned so as to show to the greatest advantage their own beauty without veiling the natural attractions of the surrounding district.

The lawn is extensive and open, the trees being in isolated groups—a rugged fringe, as it were, to the doormans, with vistas through which many "delicious peeps" are obtained. The trees are Elms, Oaks, Beeches, a few Pinusses, and very noticeable a fine Magnolia and Cedar of Lebanon, the stem of the latter girthing 24 feet. Rhododendrons appear to flourish well, and have been freely planted in the shrubberies. On this large lawn and associated with these noble trees flowers are sparsely (and it must be admitted wisely), represented. Parallel with the terrace walk on the south side of the mansion are a

Fig. 7.—BARHAM COURT.

series of chain beds, and between the walk and the building is a border where in the summer "carpet bedding" is carried out. This is the extent of the lawn flower garden, small yet sufficient.

Adjoining the mansion is a conservatory, and in connection with this structure is a commodious exotic plant stove. These at the time of my visit were *en déshabille*, both plants and houses undergoing a thorough cleansing, and the prominent feature at the moment was soap and water. The plants, however, it was easy to see, although huddled together for the convenience of the workmen, were both extensive in variety and excellent in condition.

At some distance from the mansion, at the skirt of the lawn and hidden from it, is what may be termed the flower garden proper. It is small—an ornamented dell, reached by winding walks, and it comes suddenly into view as a "pleasant surprise." This is a subtropical garden—a miniature Battersea Park. There are the raised mounds, the sheltered hollows, the informal beds, the artificial rocks, and the irregular pool as at Battersea. Indeed it seemed as if the best part of Battersea was reflected at Barham. The subtropical plants at both places were almost exactly similar, and were similarly disposed. It may be true, as Mr. Abbey has said, that Lichens and other forms of vegetation will not cling to artificial rocks; it may be equally true, as Mr. Peach has suggested, that those

rocks are but vain mimics of the "bones of nature;" but it is also true that when tastefully constructed and appropriately placed—not obtrusively prominent, but partially hidden and in subservience to other objects of decoration, that these "rocks" with the water near them, and the aquatic plants flourishing about them, enhance considerably the beauty of a "garden scene." The rocks at Barham have been tastefully arranged and answer their purpose admirably. In such places the object is not to convey a lesson on geology, but to complete a picture of varied interest and attractiveness. The "rocks" in question were "made," I think, by Mr. Pulham. They do either that manufacturer or someone else considerable credit. Such is an outline—a "general idea" of the pleasure-ground character of Barham Court, and I will now glance—it can only be a mere glance—of what was to me, as it must be to all gardeners, the far more important department of fruit-growing.

I am indebted to Mr. Record for the disappointment of a visit to this place—a disappointment, however, not of a kind that one often hears expressed after a visit of this nature. My disappointment did not arise from the fact of there being nothing to see worthy of notice, but because there was so much to see so striking and intrinsically good, and so little time for seeing it. Had I been aware of being within an hour's drive of a fruit garden so complete and novel I should have disturbed the early morning slumbers of my host, and instead

of having a "wild rush" through these fruit gardens examining nothing, I would have given that attention to them that they well merit. I have used the plural, "gardens." It is correct, for there is not simply one walled enclosure but several, devoted almost entirely to the cultivation of hardy fruits, especially Apples and Pears. There are acres of ground, miles of wire, and thousands of trees in these six large walled gardens, which I think no member of "the craft" could see without admiring. He may not admire the system adopted, for that depends on taste, and almost everyone has his fancies and prejudices; but he cannot, I think, help admitting that the system (whether he agrees with it or not) is here well and extensively carried out, and it is impossible that he can ignore the extraordinary high quality of the fruit which that system and good management produce. There are those who are powerful in their advocacy of growing fruit on the natural system; they would have no pruning, no pinching, no training. Others consider no plan equal to the bush or pyramid system, and regard both root-pruning and summer-pinching as indispensable. Others, again, are powerfully predisposed in favour of espaliers, and believe that by no other mode of culture can so much superior fruit be obtained off a given extent of ground as by training the trees to wire trellises. It is not difficult for the advocates of the respective systems to adduce testimony that each plan is worthy of adoption, and has, indeed, proved satisfactory. The fact is, that any, or all, of the plans named are good when ably carried out, and they can only be justly denounced when the systems have been or are abused.

The advocates of the wiring or espalier system—the French system—can point to Barham for evidence of its value, that being the mode which is there extensively and almost exclusively adopted. All the walls are whitewashed, and all the trees are trained as diagonal cordons, palmette verriers, or some other "Frenchified" mode of training, but the diagonals preponderate. The quarters of the gardens are devoted to espaliers, long trellises of wire being erected, running from north to south, each of the tallest being 10 feet high, with about the same distance between the trellises. These are all connected together with cross wires at regular intervals, these cross wires being fastened to the tops of the walls. These wires will no doubt be some day covered with "cordons," and will contribute much to the appearance of the gardens, and they at the same time impart stability to the whole wire-work arrangements. Some of the trellises are double, and have cordons planted on both sides, the trellises being a foot or more apart. This plan is much liked as economising space, the trees bearing as well as on the single trellises. There are other trellises 6 feet high, most of them, also the walls, being occupied with Pears. Near the sides of the walks are double and single horizontal cordons of Apples, which at the time of my visit were bearing prodigious crops of splendid fruit. There are also bush trees more or less miniature, which were bearing fruit not "miniature" but magnificent.

The Pears are fast reaching the tops of the walls and trellises, and were bearing some of the finest, if not the very finest, fruit I ever saw growing. Amongst the autumn Pears which appeared to be grown in quantity were *Bœurré Hardy*, *Louise Bonne de Jersey*, *Williams' Non Chrétien*, *Bœurré d'Amanlis*, *Doyenné du Comice*, *Bœurré de l'Assomption*, *Bœurré Superfin*, &c. Later sorts—*Pitmaston Duchesse*, *Passe Crassane*, *Marie Benoist*, *Easter Bœurré*, *Winter Nelis*, *Joséphine de Malines*, *Doyenné d'Alençon*, *Olivier de Serres*, *Prince Napoleon*, and others.

Amongst the most noticeable of the Apples were the horizontal cordons of *Api Rouge* or *Lady Apple*, veritable lines of beauty, and splendid crops of remarkable fruit of the *Winter Calville* and *Red Calville*. The finest of the *Winter Calvilles* (*Calville Blanche d'Hiver*) were produced on low cordons trained near the front of the south wall. Other sorts exceptionally fine were *Reinette du Canada*, *Reinette de Canx*, *Reinette d'Espagne*, *Cox's Pomona*, *Cox's Orange Pippin*, *Ribston Pippin*, *Belle Joséphine*, *Belle Dubois*, *Beauty of Kent*, *Cornish Gilliflower*. These are only a few impressed on my memory, for all the best kinds in cultivation are included in the collection. A sufficient proof of the high quality of the fruit produced in this garden was afforded at the autumn show at the Royal Horticultural Society, when a gold medal was awarded to Mr. Haycock, Mr. Leigh's gardener, for a collection of Pears and Apples, which for colour, size, and general high quality has been rarely equalled at any exhibition of English-grown fruit.

There is also a considerable extent of glass. Besides the

conservatory and plant stove referred to there is a vinery about 80 feet long in three compartments, Peach houses 100 feet long, Pine pit of a similar length, a span-roofed plant house also 100 feet in length, Cucumber and Melon pits 50 feet long, and an excellent orchard house 70 feet by 22 feet. The Vines were thinly trained, moderately cropped, and the Grapes were well coloured and of good quality. Peaches were gathered except *Salwey*, and the crop of this was highly superior. Figs in pots were bearing excellent crops. Melons were cut, but a fine lot of fruit of *A. F. Barron* were unused, this proving to be a good keeping variety. Pines were of medium size. Decorative plants in good order, and fruit trees in pots were numerous and excellent. Many of the glass structures were of comparative recent erection, and all were in capital working order.

The vegetable crops evidently received the same care that was bestowed on the fruit trees, the regularity and cleanliness of the several crops being very noticeable. *Asparagus* is largely grown, the plants being in hollows, with their tops supported with stakes, and the "grass" was robust and luxuriant. Tomatoes were "a sight." Stont posts had been fixed in the ground, and to these supports boards were nailed, forming a "wooden wall" 3 to 4 feet high; this was limewashed, and on the south side were trained the Tomatoes. The crop was prodigious, and certainly of greater value than the cost of the fence, while this was sufficiently substantial to last for some years.

The gardens at Barham Court are eminently worthy of inspection during the late summer months, before the fruit crops are gathered. At the period of my flying visit their cleanliness was remarkable—the white walls, the neatly-trained trees, the full vegetable crops, and the absence of weeds affording evidence that no crop was neglected in favour of another more highly prized department. The owner of this excellent garden is clearly a liberal patron of horticulture, and it is equally clear that the gardener is as skilful and attentive as the owner is earnest and liberal.—J. W.

THE TREE OR MULTIPLYING ONION.

I HAD a few given to me about four years since. Last year I had nearly half a bushel. I set in March last year 24 square feet of ground with bulbs, 6 inches apart. When I took them up in October last they quite surprised me, for at some of the roots there were three or four good-sized Onions. Besides, on the stem, about a foot from the ground, was a bunch of three or four more Onions, and above them another bunch or cluster of eight or nine smaller bulbs, about the size for pickling, and in a few instances even another cluster about the size of horse beans. We have cooked some several times, and think them milder than most Onions. They have kept well till now, but the weather being so mild they begin to grow. They are very hardy. I have had odd bulbs left in the ground all the winter grow and produce well the next summer. They are worthy of a place in any garden, for if the other Onions fail they can be relied upon, and anyone bestowing the trouble to tie them to a stake renders them a curiosity, but they do very well to fall about and grow as they like. I forked the ground over, and gave it a slight dressing of dung from the spent hotbed of the year before, and then planted the bulbs, and did nothing more to them, except keeping the weeds down.—C. E. BRACEBRIDGE, *Kilsby, Rugby*.

[This is a variety of the common Onion, and has been in our gardens many years under the name of *Garden Roccambole*.—Eds.]

OLIVE HOUSE SEEDLING GRAPE.

For this Grape the Fruit Committee of the Royal Horticultural Society at their meeting, December 6th, 1876, awarded Mr. D. P. Bell, *Clive House, Alnwick*, a first-class certificate, to which (as a seedling) he had no claim whatever. It was raised in the garden of his Grace the Duke of Northumberland at *Alnwick Castle* by *William Casley* twenty years ago, who then, as now, was employed in the forcing houses there. The female parent of it was *Black Morocco* impregnated with the pollen of *White Syrian*, for the purpose of causing the former to set its fruit better than it had been in the habit of doing. By the time that the Grapes were ripe some of the berries were noticed as being of unusual size. From these Mr. Casley saved seeds, which were sown by him and produced several plants, the fruit of some being black and of others white. After being fairly tried all but two were found to be nearly worthless. These two are still in cultivation in the houses there, that for which the certificate was awarded being

one of these two. My only motive for interfering in this matter is that honour may be given to whom it is most justly due, and that this excellent Grape may not be sent out under a false name. I may also state that Mr. D. P. Bell has only had it in his possession during the last few years.—ROBERT BOWIE, *The Gardens, Chillingham Castle.*

SPECIAL FLOWER SHOWS.

At page 24, last week, "D., Deal," says the Rose "alone of all flowers can support a distinct show for itself." This is a mistake. Several varieties of florist flowers, such as the Auricula, Tulip, and Carnation, have supported distinct shows for half a century, and they still do so. These beautiful flowers also possess this advantage over the Rose, they thrive near towns where the Rose dies outright. Some of the shows also oftentimes have a good balance on the right side. Rev. J. B. M. Camm, who knows country Rose shows well, says, in the Journal of last year, page 507, "Country Rose shows generally betray failure more or less in some form;" for instance, "Hereford, where the largest balance ever forthcoming was 4d." It ought not to be forgotten either that at the Crystal Palace on April 24th next will be held a show exclusively for Auriculas.—J. DOUGLAS.

THE PINE APPLE AND ITS CULTURE.

ALTHOUGH no longer personally engaged in the culture of this important fruit, I nevertheless look with great interest on what is being done as well as what is said relating to it. I have on more than one occasion asked for information respecting the management and culture of the Pine Apple, now imported in such large quantities from St. Michaels, and am obliged to your correspondent "M." (page 4) for his information on this point, as well as for the article as a whole; but I differ with him on the probable effect these imported Pines will have on the culture of those hitherto grown in this country. "M." seems to think that the growing of Pines will only be discontinued in a very few places, whereas I apprehend they will be given up in a great many, and their culture will be commenced in few or no new gardens, as those imported from St. Michaels being pretty good and the cheap rate they are offered places them in a favourable light with all with whom pounds, shillings, and pence have much influence, and this is a very important body. Besides which, the importers of this fruit seem fully alive to what is wanted in England; and though at first the period for which these Pines were forthcoming was a limited one it has since been very much extended, and by-and-by I have no doubt but they will be to be had all the year round. In future it behoves home growers to try and produce Pine Apples when they are most of all wanted, and especially when foreign Pines are not forthcoming. Of course the requirements of individual cases must determine what is wanted, but in general Pines are most acceptable when other tropical or choice fruits are scarce: hence the advisability of growing a good proportion of plants for winter fruiting.

Although never an extensive Pine-grower, I have always endeavoured to spread those I did grow over the greatest possible space; and how far I have succeeded may be judged by the fact, that although I only grew two kinds of late—Queens and Smooth-leaved Cayennes, I find on looking over the records of the six years ending December, 1875, there were only three calendar months during that period in which no ripe fruit was cut, these being September and October, 1872—both months in which this fruit usually is most abundant—and February, 1874; the greatest number of fruit cut in one year being in 1871, when I find 171 were cut, 162 of these being Queens and 9 Smooth-leaved Cayennes; the total weighing 450 lbs. 4 oz. swardropes, which gives an average of 2 lbs. 10 oz. each, a weight, though not to be compared with fruit usually sent to exhibition, is nevertheless very fair when all are told. I may say here that I am no great advocate for very large fruit. A Queen of, say, 3 lbs. ripened at the time of year when this fruit is in perfection is, in my opinion, large enough. Smooth Cayennes run much larger, but plants of it increase very slowly; thus I find whereas nine of this variety were cut in 1871, and all encouragement possible given to multiply and increase them, we had only eighteen cut in 1875. Of course a number of good plants were in store at the latter period, but I do not think any omitted fruiting that were expected to do so, and as we always allowed the old stools to remain as long as they furnished suckers. I merely point out how slowly this

variety propagates itself compared with Queens, as of the latter any number might have been had during that time, whereas it was customary to cut off the old leaves from the stools of Cayennes, place the plants in smaller pots, and plunge them in the warmest part of the bed. Once or twice I believe I adopted the plan recommended by some of laying the stool horizontally on a box of light soil for the shoots to rise from the side; but even that is a very slow process, and one I cannot recommend as preferable to allowing them to remain in an upright position. Might I ask other practical growers how they succeed in increasing this variety? My plants, I may observe, were all grown in pots and in a tan bed that was turned some two or three times a-year, and more or less new tan added; and about once in two years the old tan was sifted and the fine matter taken away, putting back the rough that did not pass through a sieve of something less than half an inch square in the mesh. The fresh tan was usually allowed to drain a day or two in a shed, when it was mixed with the old in the manner of trenching, which in fact the operation resembled.

With regard to the starving system, as it is called by your correspondent "M." I may say that I have found it very good practice to withhold water from some of the Queens in early summer which were wanted to show fruit as soon as possible. This, however, was only done in a medium degree, and not to the extent to deserve the name "starved," but checked; and the limited quantity of water given to the whole in autumn and winter did not render it necessary to make any distinction with these. Your correspondent is quite right about the uncertainty of Queens fruiting, for it is often provoking to see large fine-looking plants, instead of showing fruit, surround themselves with a host of suckers, most of which are not wanted. I often think those that are what I would call overpotted are most liable to this, but it is not always the case. Another evil I have sometimes had to contend with in Queens—their liability to have overgrown crowns. This I believe is often caused by too much syringing, or keeping up too damp an atmosphere in the house or pit they are growing in. Smooth Cayennes have naturally large crowns, but there is a medium in these too; and the smaller they can be made to be the prettier in my opinion they look, although in that of housekeepers in general who have the fruit to set up for table a large crown is almost as important as a large fruit. Black Jamaicas have also large crowns, but it is so many years since I had much experience with this sort that I have almost forgotten its peculiarities; but it need to be extensively grown in the neighbourhood of Manchester, where it was a special favourite.

Of the last paragraph of "M.'s" very useful article, that relating to insects, more may be said, as notwithstanding the almost thousand and one specifics for the destruction of insects, they are certainly more fatal to this than most insects are to other fruits, not but that the Pine is vigorous enough to stand against them and live; but what a life! and with what disgust does the grower of healthy good plants look upon the white-scale-covered sickly plants; and yet how often is the scale introduced unknown amongst a mass of Pines. I confess having had it twice so introduced, on one occasion the gift of a pretty variegated specimen of, I believe, the Sugar-loaf Pine, quickly infested a houseful of healthy fine plants, and a hundred fruiting-sized plants had to be thrown away and a fresh stock had to be worked-up again. On another occasion the vermin made its appearance without my having known how it was introduced, and a further destruction of plants followed. With mealy bug I have not had so much to do, but the lesson given above me in all cases when such was possible to insist on the Pine having a house or pit entirely to itself, or where Vines had to be grown in the same place to take especial care that they were free from all the pests affecting the Pine. Furthermore, I advise that all Pine houses or pits be separated entirely from structures devoted to the culture of exotic plants, as there are but few collections of those that can be called perfectly free from insects, and "prevention is easier than cure."

With regard to the difficulty of having ripe fruit in the dead winter months, there is not so much trouble this way as might be supposed. I find that the number cut during the month of December in the last six years were respectively two, nine, one, seven, eight, and two, and something like the same for January.

Having described my sufferings on two occasions with white scale, I may relate one on the other side, which though

only on a few plants is yet worth noting. It is a great many years ago when I was entering on a new situation, I found that my predecessor had left some half-dozen little suckers of Queen Pines, and for want of a better place to put them in had potted them and placed them in a plant stove with a collection of mixed plants, and, as might be expected, they were covered with white scale as thickly stuck together as it was possible. One of the best of these I shook-out of the pot, and as some horse dung was fermenting at the time prior to being used for hotbeds for Melons, I buried the plant completely in this hot dung, which I dare say ranged upwards of 100°. It remained there some twenty or thirty hours, when it was taken out and planted in suitable soil in a heated pit intended for Melons, which were also grown in the part adjoining it. This plant thrived and grew fast, quite as much so as I have ever seen a healthy plant, and no scale ever showed itself again upon it, and it eventually ripened a fruit weighing 3½ lbs., which was very fair for a Queen.

I should be very glad if someone would give us a more detailed report of the mode by which those foreign Pines are grown by which the market is at present supplied, as they differ so very much from the starved-looking West Indian fruits we have been accustomed to look upon at certain seasons during the last thirty years or more; and the fact of the geographical position of St. Michaels not being so much tropical as we supposed the Pine Apple required, I have for some time been looking for some information respecting their culture and general treatment.—J. ROBSON.

NOTES ON VILLA AND SUBURBAN GARDENING.

PRUNING EVERGREENS.—In villa gardens the pruning of evergreens is a most essential matter to attend to for more than one reason. In the first place, almost everyone makes a mistake at first by planting too thickly, and when so done by not thinning out early enough to allow those shrubs intended for permanent ornament to grow into an agreeable form. Villa gardens have generally but small spaces to devote to a shrubbery, and there must be some pruning done every year, but then let it be done in a skillful manner. I was along a street in a large town the other day where the gardens in front were planted with Aucubas, variegated and green Hollies, common and Portugal Laurels, Arbor-Vites, Yews, Eucalyptuses, and some low-growing ornamental plants in the foreground. Along this street the gardens are conspicuous for their beauty in summer, but for some time past they have been spoiled in appearance by bad pruning. Laurels have had their branches cut with a knife, and with long slanting cuts which are easily seen from the road, and to add to this ugly appearance the bare stems are many of them left from 4 to 6 inches above the surrounding foliage. Hollies and Yews have been cut with shears, and other shrubs have been trimmed in a similarly careless manner. It will be some time before these shrubs assume their former ornamental character; whereas if they had been carefully pruned in such a way as to hide every cut without exposing the stem as well, by making the cut close to the junction of a smaller or larger shoot as the case may require, the shrubs would still maintain their natural habits though confined by pruning to a smaller space. It is absurd to cut a beautiful shrub or hedge of Holly with shears for the sake of getting it into shape when it can be done so satisfactorily with a knife. The growth is not so vigorous as that of a Laurel, but is stiff and short-jointed; and by a glance at the tree, at the same time bearing in mind the shape it is intended to assume when it is finally left to itself, a selection of shoots for cutting out may be made, which will make the shrub more ornamental than it was before.

Many times it is necessary to think much before cutting, because when a shrub is not intended to be left permanently, and yet it is not advisable to part with it at once, the shoots that are cut from it should be very carefully selected, so as not to destroy the outline, and yet to give room for the shrub next to it. This is the most severe pruning of any, because it is necessary to make room for others more particular; but when the time arrives that no pruning can be done to the shrubs without spoiling them, and then instead of disfiguring them and detracting from the ornamental effect of the surrounding shrubs, I would take them out entirely.

Aucubas are easy shrubs to prune, owing to their close habit of growth. As a rule their outline is good and very natural, and the only pruning needed is in removing a few straggling shoots. Arbor-Vites require very little pruning; sometimes a thinning of the wood is necessary, but a few stakes put inside, and the shoots tied to them, will render them compact for a long time. Laurustinuses may be pruned if desired, but this being the flowering time, no pruning must be done till that is over, which is just before growth commences. I never remember seeing the Laurustinus so full of flowers as this season, and upon

shorter growth than common. I should be glad to hear if its free-flowering is general this winter, it being a mass of flowers, and when it is planted in street gardens it is a conspicuous ornament.

I see in this neighbourhood that Roses are bursting into leaf, and people are afraid to prune them yet, for the back buds are still dormant, and if pruning were done now, and the mild weather continue, these would break, and the chance of a good first bloom would be jeopardised. The Honeyuckle is in leaf also, but if this gets too forward it does not suffer like the Rose.—THOMAS RECORD.

DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

HARDY FRUIT GARDEN.

We have, as opportunity offered, continued the pruning and nailing of wall trees, and the pruning of standards and dwarfs. As for digging, or even wheeling manure on to the ground, that is not to be thought of, with the ground sodden as it is by the continued rains. The advantage of well-drained soil will be evident this year. Where the soil has not been drained in orchards, and the trees affected with lichens on the branches, this tribe of parasites will have much improved in vigour. There are two very evident causes of the growth of mosses of sorts on fruit trees—namely, crowding the trees too closely together, causing weak unhealthy growth, and planting in soil that is naturally wet without making any preparation to drain away superfluous water. There are soils drained naturally, and others can be easily drained by artificial means owing to the nature of the ground. Other soils, owing to their low lying position, cannot be drained at all. It would be very easy to say that a particular soil and position is the best for fruit-tree culture; but very few gardeners have a choice of soil, and they have generally to make the best out of the means they have at their command.

The kitchen garden at Loxford Hall is composed of soil of the very worst description for fruit trees—light sandy stony stuff over gravel lying close under the surface. It might fitly be compared to Burns' farm at Ellisland, which according to his account was formed "of the riddings of creation." Fourteen years ago there were at least a hundred fruit trees in all stages of decay, some of the Apples dying not from old age but from canker, which had eaten into the centre of the largest branches, and caused decay in those of more recent growth. Some of them could be pushed over by the hand, and no good fruit could be obtained. There was no course but to grub up the trees and replant. Where the gravel was near the surface it was removed, so that 18 inches of soil were obtained; a little heavy loam was worked-in, and some of the same substantial material was placed around the roots when the trees were planted. For several years afterwards the roots were annually lifted, and good loam placed in contact with them; the roots also were encouraged to work upwards by surface-dressings of manure being applied, and out of a large collection of the best sorts only two have been seriously affected with canker—viz., Ribeton Pippin and Dumelow's Seedling or Wellington. The first-named has become notorious for this characteristic, but the other we did not expect to fall from this cause. Pears do better than Apples on our soil; Plums and Cherries better than Pears. The tendency of all the trees is to produce too much young wood, but by careful summer pruning this adds to the production of fruit buds.

Raspberry bushes have been pruned and made ready for the ground being dug the first favourable opportunity. In the quarters of Strawberry plants weeds have been unusually productive. All we have been able to do has been to remove the largest by hand, and wait for a favourable opportunity to set the Dutch hoe to work. If trees are infested with American blight the parts ought to be dressed with paraffin; it does not seem to injure the trees or fruit buds, which boiled oil will do sometimes. The eggs of the Bombyx neustria (lacey moth) may now be found glued to the small twigs of the trees; they are compacted firmly together, and clasp closely the twigs in circles about quarter of an inch wide. They must be sought for and burned.

PINE HOUSES.

We have been re-arranging the stock in the fruiting houses. Our plan is, from a small number of plants to obtain a succession of fruits all the year round. They are not required very frequently, but it is necessary to have them on etated occasions. Under such circumstances it would be foolish to try to have a whole house of Queens to start at one time even if it were possible to do so. One house had been rested in a temperature of from 55° to 60° with a drish atmosphere, and the plants about the 1st of January were quite dry at the roots. By increasing the bottom heat to 90°, as we have done by adding fresh tan to the bed, and raising the temperature of the house to 65° as a minimum, and still keeping the roots dry, nearly all the Pines would start. We do not want this, as the pots were twice watered to thoroughly moisten the dried ball of earth and roots. The atmosphere is fairly moist, and perhaps only one plant in three will

show fruit, the others will come on at uncertain intervals during the spring months. In another house containing Smooth-leaved Cayennes and Charlotte Rothschilds there are plants with fruit in various stages of development. We had fruit at Christmas, and a few more plants will give us good examples during the spring months; more will throw up their fruit by-and-by. We do not fruit more than half a hundred plants in the year, if so many, but they are distributed as nearly as possible equally through the different seasons. When the beds are removed the bottom heat is apt to rise higher than is desirable, and the pots must not be plunged deeply unless the temperature of the bed is under 35°; and it must be seen that this is the highest point that the beds are likely to attain. Some growers do not plunge the pots at all; they add fresh tan when necessary, and merely arrange the pots over it.

Peach HOUSES.

It would save some trouble in answering questions if gardeners and amateurs would consult the "Doings," as a question is sometimes asked that has been answered in this department only a few weeks previously. For instance, it is not necessary to give instructions two or three times during the season as to washing and dressing Peach trees, surfacing the borders, watering, and other operations preliminary to forcing. If this was done when the earliest house was started, it is a waste of valuable space to repeat the directions with the second and third houses. One of the greatest dangers to which trees are subject is an over-dryness of the borders inside. The soil never ought to become dusty dry, as this causes the smaller fibrous roots to decay, a state of matters which will inevitably result in the flowers dropping off at the time of setting. The proper treatment of the trees is this: When all the fruit has been gathered give the borders a good watering; this will establish and mature the blossom buds for next year; in six or eight weeks, if the soil should be dry at the depth of a foot, give another good watering. This will usually be sufficient until it is time to start the house. It is better to water the border before applying the usual surface dressing. If this is moist before it is put on, watering a dry border through it would make it into a pasty condition and unfit it for the young rootlets. If it is put over the border after it is watered the dressing will dry a little before it is time to water a second time. Peach houses require rather more air than vineries, and the trees will not stand such a moist high temperature as will Vines until the Peaches take their second swelling.

Figs in pots have been shaken-out and repotted. It would be better to have done this in October, as the trees would have become established by this time, but they will no doubt start well and fruit freely with good management. We start in a temperature of 50° or 55°, and the pots have the benefit of a little bottom heat. Fig trees delight in rich surface dressings, and the roots work into them with marvellous rapidity when the trees are in full growth.

PLANT STOVE AND ORCHID HOUSES.

In this department it will now be necessary to advance the temperature if it is desirable to have the summer-flowering specimens early in the year. *Ixoras*, for instance, intended to flower in June should be cut down at once and be started in a temperature of 65° at least, increasing it to 70° as the season advances. Our plants have been cut down, which has given us an opportunity to thoroughly cleanse them from mealy bug and scale. Mealy bug is the worst pest of our plant stoves, and cannot be destroyed without persistent hunting-up and washing off at frequent intervals with soapy water. *Ixoras* ought to be thoroughly cleansed from this pest before the new flower buds appear; if this is not done the insects will get into the trusses of flowers, it is not then possible to destroy them without also spoiling the flowers. It is also difficult to keep the bug from Dipladenias, and equally troublesome to remove it from the leaves without seriously injuring them with the soapy water. We do not find any better way to clean stove plants of whatever kind from bug and scale than handwashing with warmish rain water in which a little soft soap has been dissolved, using a soft sponge. After thoroughly cleaning a plant it ought to be looked over in a week, and a careful supervision should be made every week or ten days after, and if this is followed up there is some chance of finally eradicating the insects.

If any choice Ferns or flowering plants require repotting this should be seen to at once; and it may be necessary first to place the potting material in the house with the plants, in order that it may be warmed before using it. If the plants are removed from a warm stove to the temperature of a cold potting shed, the check they would experience during potting would seriously cripple many of the most choice and tender.

Orchids are beginning to start into active growth. *Vandas* of the various East Indian species are showing their flower spikes, likewise *Cypripediums*. *Phalaenopsis amabilis* and *P. grandiflora* are improved by increased warmth and more moisture. Should thrips be seen upon any of them it must either be removed by washing with soapy water or fumigating with tobacco smoke. Some choice species are injured by strong tobacco fumes,

so that it is better to fumigate slightly and often than to overdo it at one time. In the Cattleya house a slight increase is also made in the temperature, and *Dendrobiums*, *Cattleyas*, some *Odontoglossums*, such as *O. citrosum* and others, which have been kept dry at the roots for the last two months, will receive rather more water. Those which are started into growth ought not to become quite dry after this time. In the cool house the same remarks hold good; but many plants in this department, and those the choicest of them, will not endure to be kept dry at any time. *Odontoglossum crispum* is in all stages of development, and we are seldom without flowers of it. Spikes are in full beauty now, others have flowers opening; some are just throwing-up, and a succession can be seen far behind the others. *O. cirrhosum* seems to be very free, and when we obtain the same strength in the plants as can be seen in the imported growths, it will be second only to *O. crispum*. Nearly all the species receive plenty of water after this. They do well with the sphagnum growing in rude health on the surface of the pots. *Masdevallias* thrive under the same treatment. The temperature of the house is about 50°, with plenty of moisture.—
J. DOUGLAS.

TRADE CATALOGUES RECEIVED.

Dick Racliff & Co., 129, High Holborn, London.—*Catalogue of Vegetable and Flower Seeds, and List of Garden Requisites.*

Charles Turner, Royal Nurseries, Slough.—*Catalogue of Seeds for the Kitchen Garden, the Flower Garden, and the Farm.*

J. C. Wheeler & Sons, Gloucester.—*Illustrated "Little Book" and Select Seed List.*

Wm. Cutbush & Son, Highgate, London, N.—*Descriptive Catalogue of Flower, Vegetable, and Farm Seeds, and Garden Requisites.*

James Dickson & Sons, 108, Eastgate Street, Chester.—*Catalogue of Vegetable and Flower Seeds, Garden Tools, Implements, &c.*

TO CORRESPONDENTS.

* * * All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

BOOKS (*Elements Ord.*)—"Cottage Gardener's Dictionary," "Garden Manual," "Thompson's Gardener's Directory."

ADDRESS (F. Green).—We do not know Mr. Trues's present address.

CORBONS (P. M.).—The reply is from a well-known fruit cultivator.

ADROUCLAS (G. S.).—Mr. J. Booth, Fallowthorpe, near Manchester.

CABBAGE LEAVES (T. E. D.).—The "underside" is that facing the soil when the leaf grows horizontally. It is the surface on which the ribs are prominent.

COYENT GARDEN PRICES (*Staines*).—The prices we quote are the retail prices. Early produce if cheap is usually imported.

CONFISERS (*Subscriber*).—We cannot name from mere leaf sprays.

BELUS (S. P. T.).—It is an Allium, and we think it is hardy and will grow in common garden soil.

BARBAROSSA GRAPE.—"J. W." wishes some of our readers who have grown it will state the result of their experience.

SPRING-FLOWERING PLANTS (*Alpha No. 1*).—All spring-flowering plants may be planted this and next month, but we should prefer planting not the early part of March, the ground being much too wet at present. Some of the best spring plants are *Arabis sibirica*, *A. alpina variegata*, *Alyssum saxatile compactum*, *Autritia grandiflora*, double *Daisies*, *Wallflowers*, *Iberis gibraltarica*, *Myosotis sylvatica*, *M. dissitiflora*; *Penny white*, yellow, blue, and purple; double *Fritillaries*, and *Gentians verna*. *Helleborus niger* and different varieties of *Hepaticas* should be planted at once. Annuals for spring flowering should have been sown in September.

ROSES SHEDDING THEIR LEAVES (*Edgbaston*).—The symptoms are those resulting from an imperfect supply of water and bad nourishment. Report (but do not disturb the ball much, only picking-out any loose soil from among the roots), in turfy loam with a fourth of decayed manure added, prodigious good drainage. Sprinkle the plants overhead twice a day, morning and evening, watering with weak liquid manure at every alternate watering after the flower buds show.

VINES IN CONSERVATORY (*A Lady Gardener*).—Plants do not generally succeed beneath Vines, the leaves obstructing the light, but as a slight shade is desirable in a conservatory, and the Vines being leafless in winter, there is really no objection to them provided they are not allowed to cover the roof too densely. In your case Vines at 4 to 4 feet 6 inches distance apart we should consider desirable. If you can command a certain supply of gas that would be the best mode of heating your house, having a gas-heated boiler with hot-water pipes sufficient to circulate round; or the house might probably be most economically heated by a boiler fixed at the back of the fire in the room, yet a separate apparatus would be best, gas being the least trouble of any.

GRUBS IN STRAWBERRY BED (H. S. F.).—It is likely the grubs will do your Strawberry plants considerable mischief. We should go over the plants, examining each separately, and destroy the grubs, making the soil firm about the plants afterwards. A dressing of gas lime at the rate of twenty bushels per acre is good against the grubs, and watering with ammoniacal liquor from the gasworks diluted with water, one gallon of ammoniacal liquor to twelve of water, giving each plant a good watering, would be beneficial.

BLANCHING WITLOFF (Idem).—Cut off the leaves to within an inch of the crown of the roots, and cover the ground to a depth of 8 or 9 inches with any light dry material, as cocoa-nut fibre refuse, sawdust, or tree leaves, placing a little litter over the latter to keep them from being blown about by wind, and the young leaves of the Witloff will come through the covering material, and from the exclusion of light be blanched, they being in fine order for salads when from 6 to 8 inches long. We take up the roots, cut the tops off about an inch above the crown, and place in rich light soil up to the crown about 8 or 4 inches apart in a dark place, with a temperature of about 55°, in which they do splendidly.

REMOVING CLEMATIS STOCK (A. J. B.).—Any time after the middle of February in mild weather, but before fresh growth takes place, is suitable. Take it off at its origin with the parent plant, being careful not to injure more of the roots than can be helped, being satisfied with a moderate amount of roots to the sucker rather than going so near the old plant as to injure its roots to a serious extent.

CAMELLIA BUDS DROOPING (J. F. C.).—Camellia with the best-formed flowers are more prone to cast their buds than semi-double varieties; but as the former are the most desirable and the defect arises from ill health or is consequent of some error of culture, we certainly should not discard any superior kinds as Congress of Ellensmers, white, striped and mottled roses, and the plea, still one of the best whites. Probably the soil border is imperfectly drained. The cause principally of Camellia buds falling is an inactive state of the roots or an insufficient supply of water after the buds are set. We do not find any compost so suitable as the top inch of a pasture where the soil is light, or the chipped up rather fine pots and rough for borders and more admirable in both instances providing good drainage and potting rather firmly. The soil is always kept moist, a thorough watering being given before the soil becomes dry. On a dry day is sufficient to cause the buds to be cast in a "shower," and suddenness of the soil causes the loss of the buds and full indication of swelling. A top-dressing of cow dung in February, or earlier, induces the roots to the surface and encourages free growth of the plants and swelling of the buds. The following are good varieties:—*Mathotiana alba*, fine white; *Deauli* (*Lecana soperla*), crimson; *Yakovarda*, rose; and *Comtesse Lavinia Magi*, white, striped and double crimson. *Stella* is also very fine, is a good compost, vegetable matter being an essential of Camellia culture. Renovate the border in February.

FORCING STRAWBERRIES (W. H.).—You will see instructions in "Doings" from time to time. Your plants ought now to be well established in their fruiting pots, and success will be problematical. The pots should be placed near a glass in the forenoon, and the temperature ought not to be more than 50° at night to start with. In cold weather 45° would be enough; gradually increase this as the plants show signs of growth, and raise it to 60° at night when the flower buds appear. They require liberal supplies of water. Forcigt shoots on fruit trees are those that grow out from the wall in such a position that they cannot easily be raised in without breaking.

GROWING PEACH TREES ON BORDER FENCE (Hortus).—There is rather a favoured district, but we cannot give you the assurance that Peach trees will be perfectly successful, still the plan is worthy of a trial. Peaches have been ripened on espaliers on a south sloping hill in Essex; we have also ripened Nectarines on a standard tree in a shrubbery. The difficulty is to maintain the trees in good health, and the winter frost is an obstacle, at night, and it is very difficult to keep aphid and red spider from them; and worst of all the spring frosts cut off the blossoms, or dull cold days and nights prevent their setting. There is no other way we can recommend except to build a wall or an orchard house.

SOWING ACALIA SEEDS (Amateur).—The plants are easily raised. If you have no greenhouse sow in pots in light loam and leaf soil, and place the pots in a gentle hotbed in March. The seedlings will come up in two or three weeks.

WINTERING ADIANTHUM CUNEATUM (Idem).—We have seen it wintered in a room where a fire was only kept in cold weather. The plant was well attended to as to watering and keeping the fronds free from dust. The potting material was composed of turfy loam and turfy peat in equal proportions with a little sand; a few bits of charcoal added is an improvement.

APHIS ON PEACH TREES (Old Subscriber).—Do not use paraffin either in the soil or on the trees. Hand-washing the branches with strong soft-soapy water will destroy the insects effectually.

INARCHING MADRESFIELD COURT GRAPE ON GROS COLMAN (Constant Reader).—If Gros Colman does not please you, traie one of the other varieties you name into the last, and the variety next to the condemned root will be most convenient. Madresfield Court is not a good variety.

VINES IN POT FALLING (X. X.).—We fancy that either the roots have been injured with too much bottom heat, or else you do not give them enough water. It is not possible to say more than this from the data given in your letter. Examine the roots and see what they are like.

EXHIBITING FERNS.—We inadvertently inserted the word "classes," which we did not occur in Mr. Shuttleworth's manuscript.

MATERIAL FOR TYING WINDWOOD FRUIT TREES (F. J.).—For temporary purposes, or to secure small trees from frost, the best material is straw admirably; but for fastening the strong shoots or branches nothing answers so well as tar twine.

TRANSPLANTING ROSES (Idem).—You may move the Roses now or next month in mild weather. Plant them next month if you can, and do not prune at least a month afterwards. In transplanting old Rose trees do not cut the stems more than you can get rid of, or only a very little, so that the roots will not be any deeper after the old settee than they were before removal.

TRANSPLANTING BRIARS (Tyro).—Briars may be transplanted until March, but the earlier they are planted the better. In obtaining Briars great care should be used in selecting stout healthy stocks. Many men who are paid so much a piece often bring in anything they can find, black, hide-bound, old worn-out Briars, which are probably many years older than themselves. You had better make an agreement to pay 1d. for each Briar, reserving the right

of rejecting all that are not likely to do well. Rose cuttings which do well will bloom next June, but they are generally inferior to Roses worked on the Mallett.—"WYLD SAVAGE.

SAWDUST (J. M.).—It is bad as a top-dressing for pastures or meadows, as it injures the Grass and is long in decaying. It is best applied to heavy and light soils. We should only mix blood with it to facilitate the spreading of the latter. Youatt on "Cattle," and Milburn on "The Cow," are useful books. We do not know who publishes them; your bookseller could ascertain.

POINSETTIA PULCHERRIMA (E. G.).—You can obtain it and the Justicia from any of the principal florists who advertise in this Journal.

NAME OF FERT (E. Bernard, Greenwell).—Blanchita the preceding.

NAMES OF PLANTS (J. Huxh).—*Sparmannia africana*. (Subscriber).—*Cypripedium barbatum*.

POULTRY, BEE, AND PIGEON CHRONICLE.

THE AQUARIUM POULTRY SHOW SCHEDULE.

We welcome the new show cordially, and wish it much success; we hope it will be annual. Only those who have experienced it know how tedious the journey is from the London stations to the Crystal Palace; and as for the Alexandria meeting, we really thought we were never going to reach it. At the Aquarium all this will be done away from, for by cab, "bus, or underground" we can arrive almost at the Exhibition's very doors. The Honorary Secretaries are Messrs. Austin and Custance. The latter gentleman we are unacquainted with; the former we believe was one of Mr. Howard's chief clerks, so he should be thoroughly master of the work before him. The Treasurers are Messrs. Jones and Pratt, and the bank is the Union Bank of England. Thus much we find on the first page; and beyond Mr. Brown, whose name is put down as the "Superintendent of poultry," we find no other members of committee, guarantors, or managers.

We were a few weeks back at a suburban show, where we for the first time heard of this proposed exhibition, and long and loud then were the tales which were circulated about this projected Show. Since then we conclude some different arrangements have been made, for we are amused to hear that those parties, then so indignant, have now gone over to the other side. We think the appearance of the inside pages of the schedule much embellished by the border advertisements of one of the Treasurers. The programme has not that clear and defined look which Mr. Howard's little pamphlet gives us. Still the classification is good, and it is fully apparent that a knowing hand has been at work among the breeds. The entry fee is 7s. 6d. per pen. We call it immense. The prizes are in most classes £2, £1, and 10s., and a 6s. fee would have been ample. Coming at the time of year as the Show does we are sure a 6s. fee would have paid the Committee much better. We cannot help quoting Oxford—we consider it *par excellence* the schedule of the day, for with a 60s. first prize the fee is only 6s., and the classification admirable. Again, we do not think it fair, neither does the poultry world generally, that the fee should be the same in classes where the prizes are not equal—viz., Bantams have 4s in every class without the chance of a cup, while Dorking, Cochins, Bantams, Game, &c., have only £3 10s. for the same fee. We are glad to see that most breeds have £5 5s. Selling classes. Such are most useful, and afford all an opportunity of buying a good and useful pair cheaply. Malays, Polish, Silkies, and Andalusians have classes, and we hope to find them all well filled. Bantams and Ducks are fairly classified. We can find no classes for Geese or Turkeys, so the north country antediluvians will have to stop at home, and fail to add another triumph to their list of prizes.

Next come the Pigeons. Pouters have half a score of classes, with the same prizes as poultry, and 2s. each pen less in entrance fee. If this is called fair we differ with such opinion greatly. Class 77 is for a champion class for Carriers (cocks) of any colour over one year, which have won not less than three first prizes £1 each. Then follow a dozen more Carrier classes for birds of 1876 and older. Dragons come next with a modest number of classes—"we are seven" being their motto. Tumblers, Barbs, and Jacobins are well cared for; while we are glad to see Fantails have three classes, the English and Scotch styles being both provided for. Nuns, Trumpeters, foreign Owls, Swallows, and Archangels each have a class. English Owls have a champion one, and those not eligible in such a class have three more to appear in. Turbits and Antwerps have each three divisions; while, thanks to our Oxford friends we expect, Magpies Black and Magpies "Red and Yellow" each have classes. Then one for any other variety, a flying class, and three for sale specimens, and this goodly Pigeon menu. A most competent staff of Judges has been selected, whose names and the classes they will take in hand will be fully found on page 5 of the schedule.

We note with much pleasure that the poultry classes have also each their Judges announced; and though in many cases we doubt if the division has been wise, still we welcome the new plan most cordially, and would tell exhibitors that as they know beforehand who will judge the various classes, so if they

enter they will have no reasonable ground for after grumbling. The entries close on the 25th, and the offices are at 172, Strand, W.C. The Secretaries request that all money orders and cheques should be crossed to the Union Bank of London. The total number of cups offered is fifty-two, which range in value from £5 5s. to £2 2s., and money may be received in lieu of cups. So far all arrangements seem to be straightforward and open, and we hope when we attend to criticise the exhibition that we may find that in arrangements and organisation Mr. Howard's cloak has fallen upon his pupil, and that all is working well.—W.

POULTRY KEEPING.

I COMMENCED some three years since, and began by purchasing expensive sittings. At the end of the first year I found myself £5 deficient in money, but in possession of a very few good birds hatched from eggs procured from Pickles, Crabtree, and Fowler. The second year, by killing off fanly and ill-shapen birds, I acquired what might be termed a fair assortment of very good birds. Having disposed of all my stock save twelve Dark Brahma hens, of ages varying from ten to eighteen months, and two male birds of the respective ages of ten and twenty months, I constructed a breeding pen consisting of three best hens and the twenty-months cock by Pickles. From these I averaged six eggs a week each; the other nine hens with the cockerel of ten months I allowed the range of a large enclosure. I sold during the season twelve sittings of eggs, besides hatching sixty-three chickens, forty-nine of which went to table. I also hatched two broods of ducklings for table use. Besides those mentioned I procured five Houdan pullets to supply eggs for table. I have still fifteen last. I had very few eggs from them last season, and up to the present (January 9th) none, although my Brahma fowls have laid regularly since the first week in December. I cannot say that my experience of the Houdan fowl is by any means satisfactory. The cost of feeding last year amounted to £12 10s., while the value of 1061 eggs (including the twelve sittings sold) and of the forty-nine chickens eaten, amounted to £15 11s., leaving a profit of £3 1s. for the season. Some of my chickens weighed 7 lbs. a couple. The food consisted of ground oats or barley meal in the morning; wheat, barley, or maize varied for afternoon meal, the mid-day meal consisting of kitchen scraps boiled with potatoes or rice. My fowls have a good grass run, ash heap, &c. I have tried Buff Cochins, Light Brahmas, Spanish, and half-bred of all descriptions, and for myself prefer the Dark Brahma to any other.—E. D.

CUPAR POULTRY SHOW.

THE third Show of poultry and Pigeons at Cupar was one of the best managed we have ever seen in Scotland. The pens were from Edinburgh, and excellent sand was strewn on the bottom, plenty of soft food and water were provided, and the birds were very comfortable.

Game headed the list with Black Red cocks and every bird noticed, hens being also good, and the winning Brown Reds good in both classes. Any other colour were mostly Duckwings, and in this class two birds were disqualified, the Judge deciding that the wing hints had been dyed to enhance the evenness of colour. One of these birds was said to be the cock to which the cup was awarded at the late Edinburgh Show, and there is no doubt but that these would have been placed first and second had they been left in a natural state. Hens were an extraordinary class. The first a sturdy built Duckwing, second a Pile, and third a Duckwing. *Dorkings* were good in both classes, the Silver-Greys especially. *Spanish* only moderate, but *Cochins* and *Brahmas* good. *Scotch Greys* were the best classes of the Show, and nowhere have we seen them as good as here, the competition being very severe, and very nice points determining the awards. *Hamburghs* were mixed classes. In Spangle cocks first was a Silver and second Gold, the main fault in this class being coarseness of comb. Hens a very good class. The Pencils were not as good as classes, but the winners fully bore out the quality of the Spangles. *Bantams* were poor with few exceptions, but there was one grand pen of Blacks.

Pigeons had few classes, but these were well filled. The White Pouters grand class, and every eye noticed, though some were lost on account of the soiled state of their plumage. Any other colour were—first Blue, second Red, and third Black. *Fantails* poor, as also the Tumblers, but there were some good Jacobins. The first in the Variety class was a Silver Dragon, second a Dun Carrier hen, and third a Black Barb. There were few good birds in the Selling class, although it was very large.

POULTRY.—GAME.—Black Red—Cock-1, J. Robertson, 2, W. McKinnon, 3, W. Cruickshanks, Hen-1, A. McKinnon, 2, J. Hall, 3, W. McKinnon, 4, W. Webster, 5, W. Webster, 6, J. Simpson, Hen-1, 2, 3, 4, 5, and 6, and 7, W. Webster, 8, C. Crawford, Any other colour—Cock-1, E. Macleish, 2, W. Cruickshanks, 3, S. Young, Hen-1, D. Simpson, 2, W. A. Swan, 3, J. Wallace, 4, J. Wishart, 5, Fisher, jun., Duckings—Silver-Grey—Cock-1, D. Aonan, 2 and 3, Admiral M. Douglass, 4, D. Aonan, 5, Mrs. Armstrong, 6, J. Rutherford, Any other colour—Cock-1 and 2, G. S. Robb, 3, Mrs. Armstrong, 4, J. Rutherford, Hen-1, Lieut.

Col. Rice, 2, D. Aonan, 3, Mrs. Armstrong, 4, G. S. Robb, SPANISH—Cock-1, A. Grievie, 2, G. Wilson, 3, J. Norval, 4, Herd & Bisset, Hen-1, A. Grievie, 2, J. Norval, 3, D. B. Murray, BRAHMA FOWLS—Cock-1, W. G. Duocan, 2, Miss M. Morrison, 3, D. Aonan, 4, A. Burnett, Hen-1, and 2, J. Sandeman, 3, J. Smart, 4, J. A. Dempster, COCHIN—Cock-1 and 2, Mrs. Davidson, 3, D. PIGEONS.—ROCKMAN—White—Cock or Hen—1, G. Henderson, 2, W. Morrison, 3, J. T. Saunderson, Any other colour—Cock or Hen—1 and 2, G. Alexander, 2 and Equal 3, A. Briggs, 4, G. Henderson, A. Glass, FANTAILS—Cock or Hen—1, J. Glenday, 2, W. H. Roberts, 3, W. R. Davidson, 4, J. Smart, 5, H. B. Marshall, HAMBURGH—Cock-1, J. M. Kidd, 2, H. C. Colston, JACOBS—Cock or Hen—1, W. & R. Davidson, 2, R. Scott, 3, A. Briggs, Any OTHER SORT—Cock or Hen—1, W. Smith, 2, A. Duncanson, 3, T. L. Johnston, 4, J. SELLING CLASS—Cock or Hen—1, T. Rodger, 2, J. Glenday, 3, W. H. Roberts.

CANARIES.—SCOTCH FANCY.—Yellow—Cock—1, J. Paul, 2, 3, Shepherd, 3, J. Stewart, 4, J. Mitchell, Hen-1, J. Wallace, 2, J. Paton, 3, Mrs. D. Black, 4, J. Paul, Buff—Cock-1, G. Stewart, 2, J. Wallace, 3, W. Mitchell, 4, A. Adamson, Hen-1, J. J. Paul, 2, J. Culbert, 3, W. Paton, 4, A. Adamson, FRENCH SORT—Yellow—Cock-1, J. Elder, 2, J. Paul, 3, P. Smith, 4, J. Culbert, Hen-1 and 2, W. Mitchell, 2, T. Curran, 4, Mrs. D. Black, Buff—Cock-1, P. Smith, 2, R. Smart, 3, Mrs. D. Black, 4, J. Shepperd, Hen-1, J. Cowan, 2, Mrs. D. Black, 3, J. Elder, 4, T. Curran, BELGIAN FANCY.—1, J. Stewart, 2, Mrs. D. Black, 3, J. Shepperd, 4, J. Stewart, FOWL-FEATHERED—Cock or Hen-1, T. Curran, 2, A. Adamson, 3, J. Speed, 4, R. M. Lauchlin, GOLDFEATHER MULES—Buff—Cock or Hen-1 and 2, W. R. Park, 3, J. Cowan, 4, G. Franks, SELLING CLASS—Cock or Hen-1, G. Stewart, 2, 1. Gillies, 3, J. Curran, 4, J. Culbert.

JUDGES.—Poultry and Pigeons: Mr. E. Hutton. Cage Birds: Messrs. Robertson and Mitchell.

ULVERSTON SHOW OF CAGE BIRDS.

This Show of Poultry, Pigeons, and Cage Birds was held in the Drill Hall on Thursday and Friday, January 11th and 12th.

The Show of Cage Birds was not quite so large as the previous one, but still the quality and condition of the birds were all that could be desired. The Belgian and Selling classes were the heaviest filled, and in the former especially were some very fair specimens. Several birds in the classes were "thrown out" for discrepancy and deficiency of feathers, among which was a Clear Yellow Norwich and three Dark Mules. A point cup was won by Mr. J. C. Salt of Burton.

CANARIES.—Belgian—Clear or Yellow-marked—1, J. Robinson, 2 and 3, J. Paxton, Extra 2, Brookbank, Extra 3, J. Moffat, Clear or Buff-marked—1, J. Moffat, 2, J. Paxton, 3, J. Brookbank, Extra 3, J. Paxton, Norwich—Clear Yellow—1 and 2, J. Adams, 3, C. J. Salt, Extra 2, D. Audley, Clear Buff—1 and 2, J. Adams, 3, Adams, Evenly-marked Yellow—1 and 3, J. Adams, 2, D. Audley, Evenly-marked Buff—1 and 3, C. J. Salt, 2, Withheld, Yorkshire—Clear Yellow or Buff—1, 2, and 3, J. Thacker, Evenly-marked Yellow or Buff—1 and 2, J. Adams, 3, Adams, Dark Goldfinch and Canary Mule—1 and 2, C. J. Salt, 2 and 3, Withheld, GOLDFEATHER—Moulded—1, J. Brookbank, 2, T. Kirkbride, 3, S. Christopherson, SELLING CLASS—1, D. Audley, 2 and 3, J. Adams, 4, C. J. Salt.

JUDGE.—Mr. G. J. Barneyay.

DOUGLAS MIXTURE.

At this season of the year, when colds, catarrh, roup, &c., are most prevalent among the poultry, one of the best preventives—and in many cases a remedy—is the well-known Douglas mixture.

As familiar as its name is to most of our readers, there are but few who know of what it is composed, and how simple a matter it is to prepare it. It consists of half a pound sulphate of iron, 1 oz. sulphuric acid, and two gallons of water. Give a teaspoonful in each half pint of drinking water.—(Pet-stock, Pigeon, and Poultry Bulletin.)

A BEE-KEEPER'S RETROSPECT.

At the close of the year, and the opening of the new year we are naturally led to take a retrospect of the past and anticipate the future. As regards "our Journal," we look out the file, and spend one or two long winter evenings not unpleasantly going over the numbers of the bypast year, successively divesting them of their advertising sheets to make ready for the binder, at the same time scanning their contents and re-reading anything of special interest. By this mode we come on many an old matter previously overlooked. We make notes as we proceed of unknown highly commended herbageous plants, &c.—those dear old-fashioned flowers, to add to our collection. We delightedly peruse all the rose lore, thoroughly enjoying Mr. Camm's rich contributions, and one or two long articles on Adam Lacharme's revenge on that cleric; endorse all Mr. Peach has

so well said on the value of Manetti and the worthlessness of the briar stock for light soils and severe winters; and have no sympathy with that "WILD SAVAGE," and are especially grateful for Mr. Hinton's invaluable rose poll; and so should you, too, Messieurs the Editors, for we made it a rule since its first appearance to present every rose-loving friend far and near with a copy, and have been thanked in return and told, "The rose poll is capital, we have (or we mean to take in the Journal)" as the case may be. We carefully studied our chief's able pomological descriptions, and again minutely revisit the ancestral nursery of Sawbridgeworth, the birthplace of our pyramidal trees; and as we take yet another look at Miss Gresswell's clever sketch of Early Wood our White and Silver-Grey Dorkings assume a fresh interest; and then we reach our own especial corner, and what have we to say of it?

We apianians have great cause for thankfulness in the year that has gone. 1876 opened most inauspiciously, with a cold backward spring advancing into as hopeless a summer. So unpropitious did it become that latterly we began seriously to consider feeding our non-swarming colonies, which by this time the straw-briars tired of doing. But the tide turned at last with such a flow as filled the hearts and hives of our little favourites with joy and gladness, commencing opportunely when the failure of the beetroot crop so raised the price of sugar as would have made a second autumnal heavy feeding a serious matter to many a poor bee-keeper.

We think kindly of "the captain on the paddle-box," and only wish he would study our old log-book more, to save we deck hands taking soundings of assertion schools to get backed off in time, remembering our log is read in America and on the Continent. Our thoughts revert back, too, to our "old captain," with many a pleasant reminiscence of his good seamanship. We trust during the present year no one will be allowed to call him hard names: he is dead, and we bronzed tars among the crew revere his memory.

We permit our Ealing Rise shipmate's interesting report of the fertile worker, we smile and chuck at why his account might be turned it than dissecting in the forecastle had he passed it fit to the "captain on the paddle-box," who offered a large round sum for its production while denying the existence of any such.

Then, again, we think with "B. & W." it very hard to deny our favourites the power of carrying the nectar of the flower right aloft into their supers without being first deposited in that intermediate state, we have as yet failed to discover.

We thought we had done, but on the last page Mr. Pettigrew while summing-up "Another Year's Experience" hazards three theoretic propositions which do not bear the test of experience. The first—"Stories are told of bees living continuously in the cavities of trees and roofs of houses. That bees live occasionally in such places a few years without attention from the hand of man I can readily believe, but having doubted that honey bees are natives (originally) of Great Britain, I have given but little credence to the stories alluded to," &c. I have been reminded thereunto that it is just sixteen years this month since I shipped on board the old craft, and curious enough my first contribution was chronicling the great success of my bees, in which high latitude I started bee-keeping some four years previously; and it is there recorded that stretches of comb foundations were measured 6 feet in length, showing that my garret tenants were not the transitory visitants Mr. Pettigrew imagines. In the roof of an old mansion in an adjoining parish I have heard of as much as a washing-tub of comb taken out on the demolition of an old colony; and in this neighbourhood bees displayed so great a partiality for the roof of a mansion, that the worthy baronet need not exclude them till he caused the slates to be stripped off and covered underneath with thick asphalted felt, heavy paper tried previously having been gnawed through. The second correspondent is also mistaken as to bees so dreading cold, if dry. Witness their survival through the most severe Russian and Canadian winters; and here in our own as well as in our neighbour's roof they always showed a marked partiality in selecting a north aspect. And why? Because they there enjoyed the maximum of winter dormancy with the consequent minimum consumption of store.

The second point. Sugar-fabricated super combs would not pass muster even if practical for super honeycombs, as it is well known to all storifiers that the presence of the whitest of the previous season's empty comb quite mars the beauty of the completed box, consequently such are only fit to contain honey for running, or more useful still, to be cut out for guide if of worker pattern. Mr. Pettigrew has repeatedly recommended employing empty drone comb for such purpose, which induces the construction of drone combs, and from the coarser appearance in supers their market value is lowered.

The third and last point is the question of the superiority of the Italian bee now olivatised in Great Britain during fifteen years; and one would think it is rather late in the day calling for competitive tests, but advanced apianians having satisfied themselves individually long ago on that point. We generally find

the sceptical as those who have preconcived them unworthy of a trial. But as I have already encroached too much on valuable space must leave over detailing some of my experiences with the yellow-jacket to another opportunity.—A RENFREW-SHIRE BEE-KEEPER.

OUR LETTER BOX.

CHICKENS CRAMPED (J. C. O.).—It is caused by the cold and wet. Keep them in the greenhouse, and give them bread soaked in ale night and morning.

CHARACTERISTICS OF ROUEN DUCKS AND BLACK HAMBURGERS (A. P. W.).—The Black Hamburg cock should have entirely black plumage all over his body, a well-formed roost comb firmly seated on the head, with a good pike behind turning upwards. Any such mixture of colour as you name would be fatal to any hope of success. All Black cocks are prone to have red, yellow, or white feathers, but they cannot be passed over. Rouen Ducks and drakes should be the counterparts of the wild Duck and mallard, no difference can be allowed. They are most frequently faulty in their bills. The Drake may have no ring round her neck. Neither Duck nor drake may have white feathers in their wings.

SPRATT'S FOOD (G. M.).—We do not know how much should be mixed with the morning meal of well-mixed mangold and barley meal (hot) for your twelve Brahms hens.

METEOROLOGICAL OBSERVATIONS.

REMARKS.

10th.—Very foggy morning and dark showery; the rain at times very heavy.

11th.—Fair, but dull and cold; rain at 9 A.M., and at intervals all day.

12th.—Fair, but thick and cold; white frost during the day; sun seen at noon, and fair at night.

13th.—Foggy, and at times extremely dark; sunny at 1 P.M.; fair afternoon, but still evening.

14th.—Dull, but fair morning; rain from noon all the rest of the day, but only showery.

15th.—Fine, dry, and bright all day; shower in the evening, but brilliant starlight night; a more pleasant day than we have had for some weeks.

16th.—Rainy morning, but fine by 11 A.M.; very bright at times, and the showers that fell were very light; the temperature much higher than yesterday.

Not nearly so warm as the two preceding weeks, but muggy and damp. Rainfall again above the average.—G. J. SIMONS.

COVENT GARDEN MARKET.—JANUARY 17.

TRADE continues very quiet, and with the exception of best goods prices rule low, with scarcely any alteration. Kent Cobs, with a short supply and moderate demand, are slightly better.

From observations taken near London during forty-three years, the average day temperature of the week is 44.5°; and its night temperature 31.7.

KITCHEN-GARDEN MEMORANDA.

VERY summer and every winter teaches us something fresh, and very often, if we are not too obstinate, it upsets previous notions and conclusions which were arrived at with a good deal of attention and study. No two summers are exactly alike, and no two winters entirely correspond. Systems of working which succeed admirably one season are found to be utterly useless the next; and plants, flowers, and fruits lauded up to the skies at one time, and perhaps honestly so, are in the short space of twelve months consigned to oblivion. It is truly said gardening is never learned, but it is very hard for a young man to believe this, and it is only after many hundreds of failures that the truth forces itself upon us and we are obliged to confess how little we know.

Some correspondents of the Journal at one time complained that we did not record our failures, but were loud enough in proclaiming successes, and implied, I think, that professional gardeners as a rule wished the world to believe that they had no failures. Of course the reverse of this is the fact. I have no faith whatever in a man who has no failures, and I know that if I were to chronicle all mine the Editors would have to enlarge the Journal and shut out their other contributors, either of which would be a great calamity. I like the Journal in its present form, and hope it never will give way to the popular failing of cramming with mere verbiage which nobody reads, or everyday science and old women's superstitions, which everyone who desires it can get in a very cheap and more convenient form at the railway book-stalls. The truthful chronicling of doings by practical men of all grades is that which distinguishes our Journal; boasting, self-laudation, and coloured reports are almost unknown in its pages, and in this respect I think it improves every year. Whether this is owing to the Editors' scissors being sharper or the contributors getting better informed, and consequently more humble, I am not able to say, but I have no doubt whatever of the fact. Although there are two or three horticultural writers whose little dainties I devour most greedily and am constantly longing for more of the same stamp, yet even for them I would not have the Journal enlarged, for I have a very great dislike to large papers and long-winded articles, and one of the greatest punishments that could be inflicted on me would be to force me to read them till my head turned round like a windmill. If my head happened to be empty it might take a considerable time to bring about this result, but otherwise the process would be very short. I could have gone into mourning a short time ago when a certain energetic little evening paper suddenly blew itself like the toad in the fable, and its friends were no longer able to recognise it except by its title. Probably if it goes on expanding it will come to the same untimely end as the poor toad. But I am afraid I am doing the very thing I am denouncing. How

pleasant it is in imagination to hear oneself speaking without interruption to all the thousands of learners from the Journal of Horticulture, who with open ears and eyes catch every syllable! But, then, Robert Burns troubles by saying, "Wad some power," &c.

From poetry to Parsnips is not perhaps an elegant leap, but I have no room for further preface. Parsnips were sown on the 25th of March, and again in the middle of June. Those sown at the latter date were good, but not so large as desirable; the former lot were an irregular crop, badly forked, and only fit for pigs. I do not recommend either of these dates, but in my heavy soil I shall be quite contented to sow Parsnips, and also Onions, any time during April, provided the ground is in good order to receive the seed.

Of Celery I consider Major Clarke's Red very far in advance of every other Celery in quality, but it is so tender that it ought not to be depended on after November. Manchester Red (also known as Sulham Prize) is a useful late kind, but it will not do to taste it till the delicate flavour of the first-named is forgotten.

I have grown Witloof Chicory, but it has no advantage over the ordinary large-rooted kind, being exactly similar in flavour, and its jagged edges are no recommendation in the salad bowl.

Two years ago I ventured to recommend the Improved Round-leaved Batavian Endive, as supplied by the Messrs. Veitch & Sons (this is altogether different from Fraser's variety, and also the old Batavian), it now not only takes the place of all other Endives, but also for winter super sedes Cos Lettuces, as it blanches better and is much hardier. When Lettuces can be had quickly grown and thoroughly blanched as we have them in summer and autumn, Endive is not worth the trouble of washing; but in winter Lettuces are generally both green and tough, and will bear no comparison with well-grown Endive, and especially the sort named above. With a little really good oil and a sliced Tomato it makes, in my opinion, without any other admixture the best winter salad procurable. Tom Thumb Lettuce is grown for kitchen purposes, and is the best Cabbage Lettuce I know.

G. F. Wilson and Veitch's Perfection are still the best Peas for quality on a good soil. Dr. Maclean is not much behind them, and will probably be found very useful on soils which are not of the first quality. It is a very vigorous and handsome Pea of medium height, and is very productive. William I. is the best early if quality is wanted.

Early Horn Carrots were sown as late as the 10th of August on a south border, and are now grown to nearly their full size. They have never been protected in any way, and although we had frost on the 1st of November which seriously injured hardy evergreens, the Carrots were none the worse for it. I find them extremely useful.

Sir Joseph Paxton is still the best French Bean for forcing, and is as good as any other for outdoors.

Autumn Giant Cauliflower is especially valuable in hot summers. Having to be planted early it roots deeply

before the great heat sets in, and is consequently unaffected by it. It requires to be sown in a frame in February and March to produce heads in August, and it is in August that the supply of Canflowers often breaks down.

Globe Artichokes planted in May as usual supplied heads till the frost cut them off, and indeed some time after, for some were cut and kept fresh by having their stems placed in water.

Very little watering was done in the kitchen garden, excepting for Celery. Peas, Beans, and the like were kept sufficiently moist by having dry litter placed round them, and they continued bearing all summer; but then I must again remind my readers that my soil is heavy, and although it has its disadvantages, last summer suited it admirably.—WILLIAM TAYLOR.

TEA-SCENTED ROSES.

A MISERABLY wet Sunday, the twentieth in succession (about that number of people at church), and no signs of any improvement in the weather. Every body looking doleful and dragged. These are not very enlivening circumstances under which to write on the loveliest flower that grows, the darling of my heart—my queen, my queen, the Tea Rose. Oh, what a time it seems since I have seen one! although they are the most constant of all Roses and are the last to disappear from my garden. How I long once more to see a Souvenir d'Elise and a Marie Van Houtte, how how many weeks must elapse before I am gratified, as I have no glass and so cannot force them.

Two correspondents want advice on the cultivation of Tea Roses, and both, strange to say, hail from a land where the cultivation of those charming flowers is a matter of some difficulty. One writes from Leek, that rosy town in Staffordshire, where I had the pleasure at the last show of meeting such enthusiastic rosarians, and the other from I know not where; at all events his roseroy is situated 2000 feet above the sea level, so that he may be said to live in an exceedingly breezy atmosphere. I will give them both the best advice that I can; but at the same time think it only fair to say that I am not handicapped in the way they are. Although I am a wild man of the woods, my abode is in mild Dorset, three miles from the sea, just sufficiently far from the ocean to get the sea air blended and subdued by that from the land. Occasionally in the spring we suffer dreadfully from the sou'westers, but that is the only wind that hurts me. But I have a little vicarious experience of northern latitudes, as my brother grows Roses in Yorkshire under most depressing circumstances; for a pall of smoke ever hangs over his roseroy, and this lies so low and so near a running foul "heek," or stream, that he suffers terribly from spring frosts, so that I am able to advise on this subject better than I should otherwise be if my lot had always been cast in this charming climate.

My experience, then, derived from observing my brother's attempts, leads me to declare that Tea Roses cannot be successfully grown in the north, or under such circumstances as your correspondents describe, in the open air without certain precautions being taken. Here I never protect a Rose, and they never want it; of course a lot die, and so do Hybrid Perpetuals, but I do not think that the weather kills them. For a time I used to grow my Tea-scented Roses under a wall, but I found that only one side of the wood ripened, and that consequently the plants did not flourish; so I now grow them in the most open spot I can find, with, of course always, a south aspect. But if I lived at Leek I should have to protect my Teas and aid them in some way or other in their conflict with Jack Frost, Enrus, Fores, &c.

If your correspondents have glass I should recommend them to take up their Teas before the winter, say in October, pot them and place them in a cold house, and not transplant them till April. My experience proves that you may plant the Tea Rose much later than the H.P. Last spring, owing to some alterations, I moved all or nearly all of my Teas in April, and put some Manetti Roses in their places.

It certainly was very late to plant Roses, and I did not expect either would do much good. The Manettie, which were purchased from one of the leading nurserymen—about five or six hundred—all died, but the Teas did uncommonly well, and most of my show Teas were cut from those plants; certainly those which won the first prize at the Aquarium were. My old man shook his head when he saw these Teas moved into the kitchen garden, and prophesied that we should do nothing with them this year; but as soon as genial weather set in they started and put forth a lot of healthy fresh wood and bore fine blooms and also (which was of the greatest

consequence to me) the blooms came about three weeks later than they would have done if the plants had been left in their original place, and so I was enabled to cut Teas for all my stands throughout the show season. If, however, your correspondents have no glass they must protect their plants in some way or other. Mr. Reynolds Hole recommends fronds of Ferns to be placed among them, or even straw could be wrapped round the stems, or screens of wood could be placed near them so as to break the force of the wind. Now, I am aware that the general custom is to prune the Tea Rose very slightly indeed, but such is not my plan. I cut my Teas as hard as my Hybrid Perpetuals, but I cut them much later.

The end of April even here is not too late to prune the Tea Rose, and in Staffordshire I should say that the middle of May would not be too late. My brother has found that unless he prunes very late indeed he cannot get a good bloom. Let, then, the weather do its worst; be patient if you can, and wait till the sun is so high in the heaven that severe frost is no longer to be feared, and then cut hard. Go down to healthy wood, even if you have to cut all your tree away and leave only a small stump, it is the only way. Badly ripened or frost-bitten wood is like a cancer to the Rose, it cannot possibly put forth healthy shoots. It must be cut out. I have a firm conviction also, that if your correspondents were to lift the Teas and examine the roots and replace them either in the same soil, or in fresh soil, about April, that they would do a wise thing.

I have given the results of my own experience, and no man can do more. I may be wrong, and very likely numbers of your readers will say that I am wrong, and perhaps some will write to you and say so. I hope they will, for nothing pleases me more than a man to tell me that I know nothing whatever about the subject of Roses, in the "Rose Journal," for then we can have a spirited set-to in print, like we did about the Rose election, and the Rose public at least will benefit, if there is any truth in the proverb "In the multitude of counsellors there is wisdom."

Now as to sorts likely to do well at Leek, that is a rather difficult matter. There are certainly some sorts which will not flourish, or which at least in my opinion it would be mere folly to attempt to grow. I do not think Cloth of Gold could succeed in the open air there, nor do I think Reine de Portugal or La Boule d'Or would do; but I am positive that the best of all Rosas (Tea and every other kind), Marie Van Houtte will do well. She is so robust, she has such vigour of constitution, she is such a darling in every way, that I feel sure she would do there. She grows stronger here than any Rose I have. I had visits from the proprietors of several Rose nurseries last summer who wanted buds of Marie Van Houtte, and I was able to cut great shoots like you would from a strong climbing Rose without injuring the trees. Souvenir d'Elise, Souvenir d'un Ami, Niphotos, Alba Rosas, Devoniansis, Souvenir de Paul Neron, Madame Willermoz, Rubens, Catherine Mermet—these, the best of the Teas, would in my opinion do, provided that protection was afforded them in severe weather, and great care and attention all the year round.

I shall be most interested to hear in the course of the year whether your correspondents have acted on this advice, and what the result has been. Of course I may be mistaken and the result may be a failure, but if so let them remember before they condemn me that I have given them the best advice I could; I have told them my own plan, explained to them my treatment of Teas, kept nothing back, shown my whole hand, and most sincerely do I wish and hope that they may succeed in growing the loveliest daughter of Flora's court, the Tea-scented Rose.—WYLL SAVAGE.

CHENOPodium BONUS-HENRICUS—MERCURY.

The following is in reply to a question in reference to the "Lincolnshire Mercury."—I can answer for the fact that this plant is largely grown in the cottage gardens of Lincolnshire. I cannot name one in particular out of the hundreds of beds of "Markwery" which are established in many villages, but there they are, and their produce is much prized by their owners, Mercury being regarded as their "first spring vegetable." This vegetable can scarcely be said to be cultivated, for, as a rule, it receives no care or assistance beyond an occasional sowing with sea-peas. It is seldom found in the gardens of the nobility, clergy, or gentry, from whence it has been driven away by the more aristocratic Spinach, Mercury being a plebeian vegetable. The Chenopodium, which is popu-

larly known as "Everlasting Spinach," is a plant of extreme hardiness and great endurance, and I am particularly acquainted with beds which have continued yielding produce for more than a quarter of a century without once having been dug up and renewed. More than once have I endeavoured to persuade the humble owners of Mercury of the superiority of the garden Spinach (*Spinacea oleracea*); but invariably after a "boiling" of the latter they have clung more tenaciously to the former than before, and I am not sure that they are not right in doing so. Mercury is a firmer vegetable than Spinach, and its flavour is agreeable. It is in use very early in the season, and is extremely productive, requiring next to no care to produce a supply. Beds are established by planting crowns during the winter, dibbing them in about 6 inches apart, when they continue to push up their growth yearly with the persistency of Dandelions or Bindweed. The *Chenopodium* is a very useful and wholesome vegetable, and is well adapted for cottage gardens.—A LINCOLNSHIRE GARDENER.

LOOKING FORWARD.

THE new year is opening before us, and we are looking forward hopefully, trustfully, and I would fain add patiently, for those of us having much tree and shrub planting on hand have need of patience in such an exceedingly wet winter. Not that we are content to sit down and wait for better times, far from that; we will never forget while looking forward that the present time is always the best time to do all we can in, not only for the present but also for the future so far as is possible; and so now while the planting must remain in abeyance, we are pushing on all such work as Vine-dressing, pruning, potting, and training plants, cutting shreds, labels, and flower sticks, sharpening pea-houghs and stakes, repairing and painting garden frame lights, making shallow boxes for cuttings and seeds, repairing netting, pot-washing, and, in fact, doing everything we can to prepare for the coming spring and summer, to both of which seasons, but especially to spring, I must own to looking forward with considerable anxiety and great expectations, for fruit trees of all kinds are so full of promise, the firm well-ripened wood being so abundantly furnished with blossom buds, that with a favourable spring, and especially after so much rain, it is reasonable to anticipate a summer of more than ordinary abundance. Vegetables and flowers may also be expected to be somewhat above par in well-drained soils, through which the almost incessant downpour has soaked with as much rapidity as it fell, leaving behind it a most precious store of wholesome, purifying, nourishing salts. Let me call the attention of such persons as have a saturated undrained soil to this important fact. All should know and understand clearly that the effect of drainage is something more than to afford a ready passage for superfluous moisture, the free unclogged soil having power to absorb and retain the nourishing salts which rain water has been proved to contain.

Perhaps the thought concerning the future in which most of us share, is regarding the effect of so mild and wet a winter upon the coming spring and summer. From the published tables of the Royal Observatory, Greenwich, extending over the greater part of a century, I find that several hot summers have been preceded by warm winters. It by no means follows that such will be the case this year. On the contrary, a cold ungenial season may follow, as was the case in 1853. Mr. Prince in his valuable book, "The Climate of Uxfield," says that "the heavy rains of 1852 and January, 1853, saturated the earth with moisture, and as the temperature of December, 1852, and January, 1853, was unusually high, vegetation during these two winter months was kept in a very warm and moist condition, which rendered it the less able to withstand the cold weather which prevailed in February, March, and April, the temperature of even the latter month scarcely exceeding that of the previous December." I hope this quotation will be regarded as "a word to the wise," and that we shall all be on the alert to see every means at our disposal to protect tender plants in the severe weather which will very likely occur before summer smiles upon us once more.

Another matter to which I am looking forward is the better management of open Vine borders in summer and autumn with the view of keeping Grapes really well. Never in my experience has there been a more trying time for Grapes hanging upon Vines growing in exposed borders than that which we experienced after the hot dry weather of last July and the early part of August. The pouring rains saturated the outside

border, and caused the sap to flow with such vigor and abundance as to burst the skins of all such delicate kinds and Madresfield Court Muecat, in many instances ruining the entire crop. It is true that something may be done to prevent the mischief by cutting the branches partly asunder, and, as Mr. Taylor has told us, in the manipulation of the foliage; but neither of these plans possess the merit of thoroughness, and it appears to me that, upon the principle that prevention is better than cure, a suitable covering for throwing off the rain must be used. I have seen and admired glazed coverings, such as Mr. Walker has at Dunorlan, and consider them quite the best for the purpose, and when made as he has them, in the form of ordinary frame lights, they can be applied to a variety of useful purposes besides. Failing these, there are many makeshifts answering this one purpose very well, such as felt stretched upon frames, and thin feather-edged boards overlapping each other, and temporarily pinned upon rafters to prevent mischief from high winds. Whatever may be the form or material of the covering, now is the time to prepare it, so that when the full flow of summer work is upon us all may be in readiness for prompt and timely use.—EDWARD LUCKEYBURN.

NOTES FROM MY GARDEN IN 1876.—No. 1.

NEITHER the size of my garden nor the excellence of my culture entitle me to say much about it, but it is perhaps because it is a type of very many possessed by the readers of the Journal that I have received so many expressions of interest and wishes that I should not discontinue my "notes;" and then I receive from time to time many novelties, or so-called novelties, on which I am asked to give an opinion, that I find it preferable to do so in this form rather than by writing special notes about them.

I was going to write that the season was an exceptional one, but then it struck me that we have not had anything but an exceptional season for a long time past. The years seemed to have forgotten quite how to behave orderly. The weather proverbs of old time, which no doubt had some foundation in fact, are entirely out of date. All out-of-door work has had to shift as it best may, and calendars of operations are only approximately correct. Thus, when we in these regions experienced that tremendous fall of snow in December, 1875, we congratulated ourselves, when our roads were blocked up and neither butcher nor baker could get near us, that we were having a real old-fashioned winter and that we should have a genial and pleasant spring. But, then, we had no spring. We were deluded into the notion that it was coming, and then came a sharp and nipping frost, or another fall of snow, or cold biting easterly winds, and this continued on until June, and then all at once we jumped into summer; and then came a broiler. The cold winds of May had prevented the growth of many things; and as they were dry at the same time, when June came there was a deficiency of grass, and in our gardens water became a prime necessity. After the drought had ceased we had some wretched weather in September, to the infinite disgust of sportsmen. The early part of October was indeed fine, but since then what a deluge! Bulbs still in their paper bags, Roses heeled-in, shrubs not moved, and the whole land either soaking like a sponge or sticky like a pudding, and so wet that neither spade or fork can be used in it. Yes, certainly it was an exceptional season. I have just (January 11th) cut a lovely bud of *Réve d'Or* Rose, which has opened in the house and is as good and perfect as in June, and there are plenty more on the tree. But then, shall we not pay for all this? And as one sees the swelling buds visions of late frosts come before our eyes; and nipped shoots of Potatoes, and fruit blighted, and flowers stripped of their beauty form no pleasing outlook for the gardener. By-the-by, in writing of our prospects in horticulture last week I spoke rather dependently of our big shows, and this week's papers unfortunately add a deeper shade of colour to this; for I see that the magnificent collection of plants of good James Cypher of Cheltenham, which have been a pride and glory of many of our provincial shows, notably Manchester, Bath, Cheltenham and Taunton, are to be sold; and that, owing to the death of Mr. Wilkins, the fine collection of specimen plants which have been quite a mainstay of our metropolitan exhibitions under the care of Mr. Ward, are to be dispersed.

And as I have mentioned Potatoes, suppose that my first notes are on this favourite root, so much valued and praised, but which, owing to the ignorance of cooks and the prejudices of mistresses, one seldom eats good. I have become pretty well

tired out of novelties which come with high-sounding claims of recognition, but which after trial one is obliged to put on one side in place of older and perhaps deeper varieties. Of new kinds this year I had only Porter's Excelsior, Bennett's Schoolmaster, and Sutton's Magnum Bonum. I do not include amongst new ones such varieties as Snowflake, Rector of Woodstock, &c. With regard to the latter Potato, I have been reluctantly compelled to discard it. It is not in this locality prolific and is delicate. I know it does not bear this character in other places, but I can only speak of it as I find it. I have now tried it for three years and with the same results, so I am reluctantly obliged to give it up. On the other hand, Snowflake has still further confirmed me in the good opinion I had formed of it. Although the season or this soil was against it, yet the produce was large in quantity and most excellent in quality. It is indeed, as far as my own experience goes, the only one of the American Potatoes worth growing: it shares their general quality of productiveness, and is devoid of that unpleasant flavour and close grain which the others, to my mind, possess. Porter's Excelsior, received from the Messrs. Carter, I found to be a very handsome Potato and prolific, always a favourite on the exhibition table, but I cannot say that it possesses the quality of flavour and texture that suit my notions of what a Potato ought to be; but then this is a matter of taste. A neighbour of mine thinks the Lapstone flavourless, and does not like a Potato that crumbles to pieces when you cut it. Bennett's Schoolmaster, received from Mr. Turner and sent out by him, is certainly a very handsome, prolific, and good round Potato. The produce was fairly good, and the quality quite equal to most of the Potatoes of the same section. In foliage it resembles some of the American varieties: the tubers are large, skin white and rough, shallow eyes, and the flesh white. It is apparently a seedling of the Regent and Victoria types, and is probably a combination of both of those excellent sorts. Mr. Turner does not send out a host of things, but when he does issue a novelty we may be sure that it is something reliable. Magnum Bonum, received from Messrs. Sutton & Sons, Reading, is a kidney Potato of great excellence. Its productiveness may be gathered from the fact that at the Reading Exhibition the gardener of Major Thoyts exhibited 267 lbs., the produce of 1 lb. of seed. The Potatoes were all of good size, there being very few small tubers amongst them, and its quality is excellent. I do not think it equal to the Lapstone, but then I do not think any Potato is. With regard to older kinds, my growth consisted of Myatt's Prolific, still to my mind the best of the early Potatoes, Regents, Lapstones, Yorkshire Hero, and Victoria. To this list I see no necessity of adding. I shall gladly give a trial to new sorts in small quantity, but on those named, with Snowflake, I shall rely for my crop.

And here let me say I, *ex animo*, endorse all that my old neighbour Mr. Luckhurst has said on the subject of early lifting, and have had this year stronger confirmation than ever of its value. It is very difficult for our cottagers to dig their Potatoes up until after hop-picking is over. But wherever my advice had been followed there the Potatoes were and have kept sound, but when lifting had been deferred until the end of October, as, indeed, I have been recommended by some writers, then disease or second growth had done its work. I am now eating Victorias which were dug up when the tubers rubbed, and some people, I have no doubt, thought me a wee bit crazed; but the tubers have kept well, are mealy and well flavoured, and fully vindicate the practice. But it is astonishing how long it takes to kill some things, and this is one of those deeply rooted prejudices which seem too firmly established to readily give way; and as long as writers encourage the notion that it makes no difference whether Potatoes are left in the ground or not, so long the practice will continue. And although my opinion may be taken for little, the trenchant character in which Mr. Luckhurst disposes of the matter will, I hope, do much towards the desired end, for it is a great pity that so large a portion of a valuable crop should be destroyed by holding to old-established practices which prove to be wrong.—D., Deat.

GLOIRE DE DIJON ROSE.

In your last week's issue your correspondent, "J. B." inquires if there are two varieties of the Gloire de Dijon Rose. In reply I beg to say that the description given corresponds with the *Tea Madame Berard*, which is of luxuriant growth, red wood and foliage. The blooms are small and of a beautiful

salmon colour, and considerably more cupped than the former. I purchased a plant of Mr. G. Paul some years since, which has furnished me with some exquisite blooms for our local shows and at the same time called forth the admiration of many visitors.—RICHARD TAPNER, *Crouchurst, Battle.*

THE CARROT.

This is one of the most common yet the most difficult to manage of culinary roots. The farmer can grow it by the acre and sell it by the ton, yet gardeners can scarcely grow as many as will supply their employers' table. Not for want of cultural skill, but from not being able to cope with what is known as the "maggot." It has been my only enemy for years. I have tried experiments, watched the Journal, and practised the most feasible preventives there set forth, including McDougall's non-poisonous "sheep dip"; still all to no effect.

Last spring I sowed Early Scarlet Horn (as I was advised) in an Onion bed, also a few in a prepared bed made of imported soil. Towards 1st of August in the latter the "maggot" began its attack, and soon accomplished its mischievous mission. The former I did not let have all their own way, for about the same date I pulled all the largest Carrots, which were about two-thirds grown, cut off the leaves about 2 inches from the crowns, packed them in a heap outside, and covered them with bog soil (moss stuff); but sand or leaf soil would answer the same purpose.

They have kept perfectly fresh, sweet, and clean from the "maggot." I let a few remain in the bed, and some weeks after they were totally destroyed by "maggot." As it is pretty generally admitted that it is almost impossible to have clean Carrots in old wrought-out gardens under ordinary circumstances, the above is worth trying, which at any rate will give a fair supply through the greater part of the winter months, not to mention the autumn, when Carrots are expected and are not always to be had. Others might record their experience—failures as well as successes. Failures serve as red lights to warn, but successes often mislead the young amateur, filling him with enthusiasm without means or opportunity to experiment.—B. G., *Co. Down.*

CHRYSANTHEMUMS FOR NON-EXHIBITORS.

MR. TAYLOR'S mode of culture (see page 25) may meet with its advocates, but I, for one, fail to see the force of his argument that "the expense incurred to grow them as they are grown for exhibition" deters numbers from growing this grand autumnal flower, and that the expense is "ten times" the amount required to grow the plants for exhibition than in growing them for home decoration. The Chrysanthemum is so easily struck and so easily grown that it is everyone's flower—a real amateur's flower—and owes its improvement mostly to amateurs, and the only necessary appliance or convenience required to grow it to perfection is a cold frame and some place of shelter from frost and rains when coming into bloom.

With these conveniences at hand we will suppose the lover of this flower has some old stools which have done blooming. What are to be done with these cut-down old plants from the time of going out of bloom until the "last week in May?" Attention, time, and "expense" are required to preserve them; therefore where is the great difference in "expense" between taking cuttings as soon as ready and throwing your old plants away, thereby reducing your stock to a minimum, and having your pots wherein they bloomed at your disposal for growing many other plants? If Mr. Taylor could assure finer blooms apart from the "expense" I would give his plan a fair trial; but with early-struck plants the cultivator has the assurance of well-ripened wood, without which it is impossible to obtain the desired "perfection of bloom and as large as Dahlias." Apart from this the uninitiated in the culture of Chrysanthemums are more likely to err on being driven to so short a time than if a longer time were advised for the encouragement of root-action and the maturation of the wood.

Mr. Taylor's treatment of twice stopping is very good and worthy of imitation, and has been practised by Mr. Turner of Slough and other cultivators, but this stopping should not be performed later than July with many sorts. Small plants are sometimes propagated as late as August, but these are not expected to carry blooms as large as Dahlias." Again I say to those who have a wish to grow the Chrysanthemum, whether for home decoration or exhibition, put in your cuttings as

soon as they are ready, and when you have taken as many as are wanted throw away the old plants if not required, and for the small cost of growing the young plants from now till May you will be more than compensated during the dark and foggy days of November.—J. W. MOORMAN.

FLOWERS WORTH GROWING FOR CUTTING.

Ageratum Imperial Dwarf.—Lavender, half-hardy annual. Seed should be sown in a hotbed in March, the seedlings potted-off singly in 3-inch pots when large enough to handle, and be grown-on near the glass in gentle heat, hardening-off thoroughly before planting-out in May. The soil requires to be rich and light, an open yet sheltered position, planting three rows in a 4-foot bed, or plant in rows 1 foot apart, omitting every fourth row. Water freely in dry weather, and occasionally with liquid manure after the plants commence flowering. 18 inches.

Aster.—Victoria and Improved Pæony Perfection, those being best had in collections, or if only a few are wanted mixed packets will serve. If but one kind is wanted the Victoria is very much the best; and of the Dwarf Bouquet the Boltze Aster is superb. Sow in March for early bloom as described for *Ageratum*, and for a late bloom early in April in a cold frame, keeping close until the plants just show through the soil, then admit air freely, avoiding frost. The plants will be very stocky, and should be planted-out late in May or early in June. The Victoria and Pæony Asters should be planted in rows 18 inches apart, omitting every third row for an alley, and the Bouquet Asters in rows a foot apart, omitting every fourth row. The soil can hardly be too rich for these plants, and the plants are the better if mulched with short manure, and have weak liquid manure after they "button."

Centaurea Cyanus major.—Various-coloured, mostly blue and white, or light shades of colour; one of the finest of all cut flowers. Hardy annual. Sow during early April in light rich soil in an open yet sheltered situation in rows a yard apart, thinning-out the plants to 6 inches apart. I like a double row, the rows being about 6 inches apart, and the plants that distance in the rows. The dwarf—i.e., minor, is not nearly so good as the tall variety. Sow early in September in a sheltered border to stand the winter for early summer bloom. 3 feet.

Chrysanthemum.—C. Dunnettii flore-pleno (double white), C. Dunnettii aurea (double golden), and C. carinatum hybridum flore-pleno (various-coloured), are useful hardy annuals. Sow in March for early bloom in gentle heat, treating the same as Asters; and sow out of doors early in April in rows a foot apart, thinning the plants to 9 inches. 2 feet.

Marigolds.—These are neglected for cutting. Why? They really are very beautiful. The great African Orange and Lemon Marigolds are really superb by candlelight when arranged with the feathery spray of *Colecia pyramidalis* coccinea or dark Fuchsias, whilst the Striped French Marigolds have the finest marking. Sow during early April in gentle heat, keeping near the glass to prevent the seedlings from drawing, potting-off singly or pricking-off in pans or boxes 2 or 3 inches apart, sowing well so as to have stocky plants well hardened-off by the middle of May. They like good rich soil and the distances mentioned for Victoria Asters are suitable. 2 feet.

Mignonette.—Large-flowered Pyramidal (*Reseda meliorata gigantea pyramidalis*), surpasses all others. Sow on a warm border in March for early bloom, or in pots, planting-out in May after hardening the plants well off, and early in April sow in drills 18 inches apart, thinning the plants to 9 inches apart. Mignonette likes a free, open, rich soil. I sow mine in borders like Parsley. Enough seed may be had for a shilling to form a row more than 100 yards long 18 to 24 inches wide, no plant for the money affording so good a return in delicate fragrance.

Sweet Peas.—These are unquestionably unapproached by any annual for cutting, for which purpose they are best grown in separate colours, but for effect the colours should be mixed. It is surprising what a quantity of flowers a row 20 yards long will give, and everybody should have a long row of these Sweet Pea blooms. For early flowering seed may be sown in pots or on reversed strips of turf and grown in a cold frame, planting-out in April or early in May in a warm situation, sowing outdoors early in April, and for succession early in May. They require sticking like edible Peas, and grow 6 feet high. Afford them rich soil, and liquid manure after commencing flowering.

Phlox Drummondii.—It is best to obtain a collection, the

colours are very rich and varied, and the flowers are very durable in a cut state. Sow in March in gentle heat, pricking-off in pans or boxes about an inch apart, hardening the plants well off before planting-out during May, in an open situation in light rich soil, the rows to be a foot apart, omitting every fourth row. Water freely in dry weather. 18 inches.

Scabious (Double Dwarf).—The colours of the flowers are rich and showy, and possess a delicate fragrance. This old plant, especially in its newer dwarf form, is not nearly so common as it deserves. It is also very enduring in a cut state. It is a biennial, and may be sown in June outdoors in an open situation, pricking the seedlings out in a sheltered place during September, and planting them out in spring, or they may be left to flower where put out in late summer; but it flowers the first year grandly if sown in March in gentle heat, the plants being hardened-off before planting-out in May. I have sown in a cold frame in early April, and had good plants to put out in May, flowering finely in August until severe frost. They require the distances named for Victoria Asters. Scabious ought to be in every garden.

Stocks.—Large-flowering German Ten-week, secure a collection and sow in March in gentle heat, pricking-off the plants when large enough to handle; but they will repay potting-off singly in small pots, and after being hardened-off planting out in May in rich soil. The rows should be a foot apart, omitting every fourth row. They will bloom splendidly in July. Sow again early in April in a cold frame and plant out at the end of May or early in June, and they will bloom in August and continue until frost. Intermediate Stock is best represented in Eset Lothian, purple, scarlet, and white, which should be sown in July or early in August, established in pots before winter, wintered in a pit or frame with protection in severe weather, shifting into larger pots in February any which are intended for greenhouse decoration, planting out the remainder after the weather becomes mild. For late summer sow during March in gentle heat and plant out during May. The soil for Stocks should be rich and light.

Sweet Sultan, purple, white, and yellow, yields sweet and showy flowers. It should be sown in rich light soil early in April where the plants are required to flower, in rows 18 inches apart, the plants allowed to stand in a double row about 6 inches apart, 2 feet. Sow in early September for early flowering—in fact, autumn sowings give the finest flowers.

Wallflowers.—Harbinger is the earliest variety, flowering finely in autumn from seed sown in March or early April, and continuing through the winter when mild. It is a brown or reddish brown. Belvoir Castle, dwarf yellow, is very floriferous, and it with Blood Red will meet every requirement in the single-flowered section, and of the double German varieties a collection must be obtained to secure good flowers. Sow in May or early in June, pricking-off the seedlings when large enough to handle in rows 6 inches apart and that distance between each plant, and in September take out every other row and every other plant in the rows left, and plant a foot apart where intended to flower. The soil for Wallflowers should only be moderately rich and the situation sheltered, the ground being open in character though firm, so as to induce a stiff well-ripened growth, for when the soil is rich and loose the plants are so succulent as to be cut by frost.

Branching Larkspurs give a number of side shoots that are very useful, especially the blue or purple shades of colour. Sow during early April in an open situation in rows 2 feet apart, omitting every third, thinning the plants to 6 inches apart. 2½ feet. Sow in September for early summer cutting.

The Perennial Larkspurs or *Dolichnum* if sown early, or during March in gentle heat and the plants pricked-off 2 inches apart in pans or boxes when they show the second leaves, and grown-on, hardening well off and planting out during May in rich soil in an open situation 18 inches apart, will flower in late summer, and being mostly blue shades of colour are very desirable. 3 feet. The French hybrids are very good, a packet usually giving some variety. *D. formosum* is fine, and *D. nudicaule* (scarlet), *D. chinensis* (deep blue), and *D. grandiflorum* celestinum (sky-blue) are all worthy of cultivation.

Rockets are very free-flowering and sweet. The purple (lilac) and white are good, but the brown or sweet (*Hesperis tristis*) is most perfumed. Sow in May or June outdoors, pricking the plants off when large enough to handle, and plant out during September 18 inches apart in light soil. 2 to 3 feet. They flower in early summer.

Jacobaea (*Senecio elegans*) in double crimson, lilac, purple, red, and white, give an immensity of flowers which are often

very useful. Sow in March in a hotbed, prick off the young plants 2 inches apart in pans or boxes, hardening well off, and plant out in May 18 inches apart, omitting every third row. Many others besides the preceding I have known improvised occasionally for cutting, such as *Tropeolums* of the Lobbianum section, as Brilliant, Glory, and Elegans. They are easily raised by sowing in gentle heat in March, potting the plants singly and planting out after hardening well off in May, supporting with stakes or trellises, the plants also doing well on rockwork, banks, &c. I shall close by mentioning Zinnias, which are useful, requiring the treatment of Asters.—G. ABBEY.

NOTES AND GLEANINGS.

EARLY in the week the barometer was higher than it has been for many months past, and sunny days have at length arrived. The nights have been frosty, but in the neighbourhood of London the frost has only been slight, sufficient to check advancing vegetation without doing any injury. The ground has dried rapidly, affording an opportunity for bringing up arrears of garden work, and the bright days have been of great benefit in the forcing department. We have several accounts of Vines "breaking weakly," a circumstance due probably to a deficiency of light, and brighter days may be expected to bring general improvement.

A YEAR ago we noticed that Mr. Wills was appointed fiscal manager of the ROYAL WESTMINSTER AQUARIUM AND SUMMER AND WINTER GARDEN SOCIETY; we have now to announce that he has relinquished that position. For a long time the "aquarium" was without fish, but the "garden" has never been without flowers; nor have the plants used been merely showy plants of little value. The plants for permanent effect have been introduced at great cost, such as Tree Ferns, Palms, Mosses, &c., while flowering plants have been employed in great numbers and of superior quality. Mr. Wills continued his duties worthily until the last day of his term, on which day he rendered the great hall attractive by tastefully-arranged groups of hundreds of Hyacinths in separate colours, Tulips, Narcissuses, Primulas, Lilies, Echeveria retana, &c., the colours being divided by bands of *Lycopodium denticulatum*, which covered the undulated surface of the ground. On mounds and knolls were choice Palms and Pandanus, and the effect produced was excellent. The entrance hall, however, was not decorated; the dry air, and fringe of gas jets (for spectacular effect) had wrought such ruin to valuable plants that it was deplorable to witness. The plants which have suffered the most are Dicksonias, Cyces revoluta, Sessiforthias, and Lstania. Fine specimens of those are irretrievably ruined. A few which have not succumbed are *Aspidarias*, *Green Dracenas*, and *Pandanus utilis*; but unfortunately the plants which have cost the most have suffered the most, and their condition cannot but be viewed with regret by all who know the value of the specimens.

DURING last year Dr. Newington informs us that at Ticehurst, Sussex, there fell 33.95 INCHES OF RAIN, and that this year up to the 18th inst. 6½ inches had fallen.

AS an instance of the mildness of the weather and the FORWARD STATE OF VEGETATION we noted in Messrs. Charles Lee & Son's nursery on the 19th inst. a tree of *Pyrus sinensis* almost opening its blossoms, and on another tree of the same Pear some young foliage fully expanded. We also observed some young shoots of variegated Elms 5 inches in length. In some of the sheltered villa gardens near London bedding Geraniums are still not only alive but growing, having pushed shoots at the several joints of the old stems fully an inch in length. We noticed *Ceanothus azureus* flowering on a wall at Isleworth; and *Veronica Blue Gem* is still flowering freely in many gardens.

THE flowering sprays of *CHIMONANTHUS GRANDIFLORUS*, which were exhibited last week from the Royal Horticultural Society's gardens, were worthy of more than a passing notice. *C. fragrans* is deservedly popular as a hardy, fragrant, mid-winter flowering plant; but *C. grandiflorus* greatly exceeds it in the size of its flowers. The sprays referred to were covered with buff-coloured blossoms, and were highly attractive, while their Jonquil-like perfume was delicious. The *Chimonanthuses* are easily grown, but do not always flower profusely. To induce flowering the shoots should be thinly trained to a sunny wall, and the growths should be regulated by summer pinching. When the wall space has been covered, it is a good plan to dig up the plant and replant it, and the check it receives by that

operation is almost certain to accelerate its flowering. A plant of *Chimonanthus* should be in every garden where a sunny site is provided. A dozen of its modest flowers are sufficient to perfume a large room. Although the plant is quite hardy, a little protection is necessary during the flowering period if the weather at the time is severe.

A MEETING of the Committee of the NATIONAL AGRICULTURAL SOCIETY'S SOUTHERN SHOW will be held at the Horticultural Club, Adelphi Terrace, Strand, on Wednesday, January 31st, at one for two o'clock, to receive the report of the Sub-committee appointed to draft a schedule of prizes, and adopt or reject the same. A meeting of Carnation and Picotee growers will be held at the same time and place.

THE LATE STORMS and HIGH TIDES have done much damage in the neighbourhood of Fulham. Commencing at New Wandsworth Bridge, Mr. Steele, the market gardener, has suffered to the extent of some hundreds of pounds. Celery ridges were washed away, also large beds of *Sesalix* stacked ready for forcing. Radish beds, &c., were destroyed. Messrs. Veitch have suffered through their Peterborough Lane Nurseries having been under water. The grounds at Hurlingham House have also been entirely under water. At Mulgrave House, the residence of Lord Ranelagh, damage to the amount of £300 has been done. Breaches have been made in walls, &c. At Grass Bank, a pretty little place adjoining the Bishop of London's palace, is now a total wreck; the camp siding has been washed entirely away, and a large portion of the garden with it. Besides the damage done inside the house at Craven Cottage, a large and massive wall erected since the last high tides has been swept entirely away, with a conservatory adjoining. Large Elm trees have been blown down at the Bishop of London's, also the walk known as Bishop's Walk has been partly washed into the moat. The suffering of the poor of Fulham is intense. Several houses are vacated; in fact, the Board of Works considers them no longer fit for habitation.

AS to the hardness of *LYCOPodium DENTICULATUM*, inquired about on page 8, Mr. Luckhurst says "it has been established in the rock garden at Newick Park for so many years that the date of the first planting is unknown. The position is certainly sheltered by trees, but in a low and exceedingly wet valley like that there must be many degrees of frost in a severe winter, and which this *Lycopod* always withstands, the only perceptible effect of cold weather being the loss of its bright green hue, which, however, it soon regains in spring. "J. N." would do well to give this pretty moss another trial, planting several of it in different positions, and I have no doubt his efforts will eventually be crowned with success."

WRITING to us on EXHIBITING PEACHES, "A YOUNG FRUIT-GROWER" suggests that the fruit should be tasted and let quality have its due weight, the same as is the case with Melons and Grapes. Our correspondent remarks that "when Early Crawford Peach is exhibited its imposing appearance secures for it premier honour, and it receives in consequence a fictitious fame;" for with many growers, himself amongst the number, this Peach "is neither constant in producing a crop, nor is the fruit of high quality when produced." This suggestion is worthy of the notice of fruit judges, who do not, we believe, as a rule, taste the Peaches on which they adjudicate.

NOTHING is MORE EASY than to DESTROY MOSS ON THE BRANCHES OF FRUIT TREES. When the branches are wet fresh-slaked strong lime thrown freely amongst them will adhere and destroy every vestige of moss. This is far more effectual than using the lime as a wash—applying it with a brush. The lime falling to the ground is also beneficial. In all gardens where moss is prevalent lime should be annually dusted amongst the Currant and Gooseberry bushes and fruit trees after they have been pruned, and before the ground is dug, and cleaner branches, healthier trees, and finer fruit will follow. The lime is also useful in protecting the fruit buds from birds. A man will do more execution in one day in destroying moss by thus dusting with lime than will another man in a week with the "whitewash brush."

A FEW inches of partly decayed manure spread over the roots of fruit trees in autumn would do much toward preventing the MOISTURE FROM EVAPORATING and HEAT FROM ESCAPING. The cold wintry winds will dry out the soil as certainly if not as rapidly as the warm winds of summer, and a mulch would be a beneficial protector. Trees planted but one or a few years would be especially benefited by a mulch covering the roots from the trunk outward. We would mulch to prevent the

escape of heat as well as moisture from the soil. If an animal is ever frozen, it is because of the escape of heat from its body. The human body we cover with warm woollen clothing in winter to prevent the too free escape of heat. Nature clothes the brute with hair, fur, or feathers, which grow longer and thicker in winter than in summer, thus securing his comfort. When we see how much nature has done to prevent the too great reduction of the animal temperature, may we not take the hint and do something to prevent the escape of heat from the soil in which is embedded the roots of trees and plants?—(Rural Home.)

M. MOUILLEFERT, a professor at the School of Agriculture at Grignon, has been making experiments for the purpose of determining what agent was the most practically applicable to the destruction of the PHYLLOXERA. After trying many substances it was only with some of the sulphur compounds that really satisfactory results were obtained, and it is to M. Dumas, the permanent secretary of the French Academy of Sciences, that the credit is due for suggesting the employment of the alkaline sulpho-carbonates of potassium and sodium and those of barium and calcium. All the other remedies tried were either without effect on the Phylloxera, or, in destroying it, also destroyed or damaged the Vine. But the task of eradicating the Phylloxera has by no means been accomplished by the mere discovery of the value for the purpose of these substances; there is the further difficulty of applying them to the Vine in cultivation. One thing seems very certain, that in order to render the sulpho-carbonates practically efficacious in killing the insect, it is necessary to use water as the vehicle by which they may be brought to all the underground parts of the plant, and that the best time of year for their application is the winter or early spring, when the earth is still moist and the quantity of water necessary to be brought on to the ground by artificial means is consequently less. The conclusion at which M. Mouillefert arrives is that the efficacy of the sulpho-carbonates is proved, and all that is necessary is to bring to perfection their employment in agriculture, which can only be accomplished by the intelligence and practical knowledge of the Vine-grower, who is well able to discover the economic processes of culture which are conducive to their successful application. He ends by saying that "Science has accomplished its mission, and it remains for Agriculture to fulfil its part" in the eradication of the Phylloxera from the vineyards of France.—(Nature.)

THE ROYAL HORTICULTURAL SOCIETY'S GARDENS.

We copy the following from the Times:—

The Royal Horticultural Society has recently suffered so much from untrue statements damaging to its reputation, that I trust you will permit me to state in your universally-read columns what its actual position is.

1. It is a chartered corporation, of which the members—*i.e.*, the Fellows, cannot as such incur any personal liability beyond that of paying their subscriptions while they continue Fellows.
2. Its debentures are a charge on its surplus income after payment of its expenses only, do not attach upon any of its property, and do not constitute a debt. Of debts for which its property is liable it has none, and it has long since met all its engagements in respect of prizes and medals.
3. It has never ceased to do, and is now doing, good practical work for the advancement of horticulture at its Chiswick Gardens, as its published reports testify.
4. The Council have determined to continue the South Kensington Gardens on their former footing, and to make them as attractive to the residents in their neighbourhood and of London generally as the means and nature of the Society will permit. They have extended the privileges of their Fellows, and, subject to the approval of a general meeting, have determined to remit for the present entrance fees on election or re-election of Fellows.
5. If the subscription income of the Society for next year be raised to £10,000, the South Kensington Gardens will be secured to it certainly until 1892, to the great advantage of the residents and owners of property in their neighbourhood. If such income be not raised, those gardens will pass into the possession of the lessors, and probably be built over.
6. To place the Society in a more prosperous and secure position than it has ever occupied, nothing more is wanting than, for the present year, a renewal of a part only of the subscriptions which have recently been discontinued, and for the coming year an effort which wealthy South Kensington would scarcely feel, and which will raise the £10,000 above referred to.

I would therefore ask all who wish to preserve the gardens, and all who love horticulture, to lay aside their unfounded distrust of the future of the Society, and, forgetting old quarrels, to join in making it stronger than ever. The Council are trying, so far as their funds will allow them, to meet the wishes of their London Fellows. The principal western entrance has been reopened; the gardens, which have suffered nothing that a few days' labour will not repair, are being put in order; and the bands and promenades in the conservatory will be resumed on an early date.—Your obedient servant, ROBERT HOOD, Secretary, Royal Horticultural Gardens, South Kensington, W., Jan. 18th.

THE ORIGINAL WELLINGTONIAS IN ENGLAND.

In company with that first-class rosarian and well-known horticulturist, Mr. James Walters of Exeter, I have to-day been to see the Wellingtonia mentioned by your correspondent J. W. Moorman, in your paper of January 11th. As Mr. Walters was with old Mr. Veitch when the first seed was germinated, and recollects the fact well, he had no difficulty in pointing out the tree to me, though he could not recollect the date (probably from 1855 to 1858). The tree is not in first-rate condition, nor can it be called a first-class specimen. As the sun was not shining at the time I had a boy to climb the tree with a cord, which he drew tight when he was within 1 foot from the top, and I have thus ascertained the height to be 14½ feet, the girth of the trunk immediately above the bole was 10½ feet. The tree grows in a somewhat confined place, consequently the circumference of the branches is not large. I have observed in many other specimens that when the tree is planted amongst other trees it runs up with not much greater breadth than a Lombardy Poplar.

In the same grounds (Mr. Lloyd's, Mount Radford, Exeter) Mr. Walters pointed out to me another tree of the same kind, and even more interesting than the last. It is the original plant brought over by Mr. Lobb from California. For many years it was grown in a tub, and consequently, I suppose, has not attained the size which might have been expected. I took its dimensions also. Favoured by a bright gleam of sunshine I measured the length of its shadow and that of my stick (exactly 1 yard long), and the result of my calculation was that its height was 31½ feet, but its circumference was 8½ feet, and a more perfect cone and a more magnificently furnished tree I never saw. Its verdure and perfectly healthy appearance were equally remarkable.

In respect to height there are in this neighbourhood many higher Wellingtonias, notably some in Eggesford Park and some in Credeney Park (Sandford), but I have seen not one which can compare in beauty with the original plant imported by Mr. Lobb.—SENEX CORVICUS.

ECHEVERIA RETUSA.

AMONGST all the species of Echeverias there are very few can equal this as an exceedingly useful greenhouse plant, and if cultivated in quantity so as to come in bloom at the present season it is doubly valuable.

It is of easy culture, being within the power of anyone who has a small greenhouse. It is best propagated by cuttings in the spring, and then grown-on in the summer, so that the plants may be well established before autumn, and they will soon show flower when introduced into the greenhouse. I use a mixture of loam, leaf soil, and lime rubbish, and some charcoal dust—a compost which the plants luxuriate in. I have some plants now in bloom in 8-inch pots with twenty principal flower stems, and numbers of smaller plants in 5 and 6-inch pots with from four to eight stems on each. It is extremely useful for cut flowers, and will last fresh and good for weeks.

I find an easy way of growing dwarf plants is to propagate early in the spring, and plant them out at the end of May on a place well exposed to the sun, and the plants will take care of themselves until autumn, when they must be taken up with balls and potted before the frost injures them.—J. A. Hill Grove.

P.S.—I enclose a flower of the Eucharis amazonica. The tubes of the two flowers are attached to each other, yet each flower is fully furnished with all the organs of fructification. There were nine spikes of bloom on the plant growing in an 8-inch pot, and there is from four to five flowers on each spike, making an aggregate of about forty flowers. It is a magnificent white flower for the dull winter months, and if the blooms are cut when fully developed they last a considerable time in water.

The culture of this beautiful Lily has been fully described in your pages in previous numbers.

SCHIZOSTYLIS COCCINEA.

CRIMSON SCHIZOSTYLIS.

This plant has been frequently mentioned during the past year. It is thus noticed in the "Botanical Magazine." It seems

Fig. 8.—Schizostylis coccinea.

to have been first flowered by Messrs. Backhouse & Son at their nursery at York in November, 1863. It inhabits eastern rivers of South Africa, called Kabonise and Keir-kamma, in Kaffirland. Dr. Harvey possesses specimens of the same plant gathered by Cooper near Drakensberg Mountain; and also from Mr. D'Urban, who found it by the Kabonise river in British Caffraria, in both cases growing very near water.

Again, Dr. Harvey has detected it in Mr. Sanderson's collections from Natal, and in Mr. Hutton's from the Katberg, altitude 3000 feet, who speaks of it as a "beautiful pink Heperantha," showing its affinity in his eyes to that genus, to which Mr. Backhouse also detected a resemblance.

It is a plant of great usefulness, affording brilliant spikes of flowers during the autumn months. These are effective for the decoration of vases in rooms, the flowers expanding in water after the manner of Gladioluses. The plants are also very valuable for conservatory decoration during the late autumn and early winter months. When employed for this purpose clumps only need to be dug from the open ground early in October and potted in light rich soil, and if placed in a genial temperature flowers will be produced until Christmas. The plant is hardy and will grow freely in ordinary garden soil. It is highly worthy of extensive cultivation.

ADIANTUM CAPILLUS-VENERIS—LANDSLIPS.

I REMEMBER one year judging at Hereford with Mr. Charles Turner and Hercules. We had some bouquets to judge which were composed of Roses and wild foliage. One lovely bouquet was made up of Maiden-hair Fern, and I objected to it as not being wild foliage. Mr. Charles Turner, however, said that he did not think we could disqualify it, as the Maiden-hair Fern did grow wild in some part of Devonshire, although, he added, there could be no question it did not grow near Hereford. So we gave (unwillingly) the bouquet the first prize. Since then I have tried to find this Fern, and have asked large Fern-collectors if they have ever found it wild. There is rather a celebrated collector at Lynton in North Devon, and he told me he had walked all along the north coast of Devon and Cornwall looking for it in the places where it was reported to grow luxuriantly, and he could only find one small plant near Boscawen. Judge, then, of my surprise and delight when a lady of my acquaintance found this Fern (*Adiantum Capillus-Veneris*) growing in the lane that leads from the Charmouth road to my church, in the very hedge that divides Devon from Dorset.

I write this for the purpose of asking any of your readers if they know of any other places where this Fern grows. I am told that it is to be found in the neighbourhood of Bridgewater.

One of the Editors of our Journal will be interested in hearing that there have been several fresh landslips at and near Lyme Regis. An immense amount of earth fell on the Esplanade at Lyme, completely blocking the road; whilst at Whitlands, the farm next to Dowlands (where the great landslip is), about seventy acres have subsided, and some cottages have been rendered so unsafe that the occupants have had to leave. The road, too, from Charmouth to Lyme is quietly settling into the sea.—WYLD SAVAGE.

ANEMONE FULGENS.

FOR the information of "G. S.," in notice to correspondents, page 538 of our Journal, respecting *Anemone fulgens*—I do not disturb my plants. They are grown in a full exposure to the sun, planted by the edging of the beds in our flower garden; in that position they are quite at home, and during the spring time reward us with a profusion of brilliant flowers. Glowing as the description may have been that "G. S." has read, it cannot convey an adequate idea of the effect that is produced by lines of this, one of the most striking of our spring flowers. It ought to be in every sunny flower border in the three kingdoms, for we have no flower in cultivation that can surpass our Windflower in early spring and summer time. The soil in which the plants are growing is good loam mixed with leaf soil and coarse grit.—H.

EARLY WRITERS ON ENGLISH GARDENING.

No. 26.

JAMES LEE.

JAMES LEE was one of the best gardeners of his time. He was born in Scotland of respectable parents, but not in a station that allowed them to give him any farther education than is in the power of everyone to attain in that part of Britain; and which, at that period, was generally superior to what those of that rank in England can arrive at. He discovered very early a strong taste for botany, and we are warranted in asserting that when a youth of fifteen or sixteen he was well acquainted with

English plants, the knowledge of which he had acquired principally by the assistance of Culpepper's "Herbal." Being endowed by nature with strong parts, a retentive memory, and great perseverance, he made himself master of the Latin tongue, and became well acquainted with the Linnæan system in an early stage of life. This knowledge, indeed, of the sciences was in the end not superficial or the mere routine of gardeners in general at that time; but having accurately studied the principles of the science as exhibited in the "Philosophia Botanica" of Linnæus, he undertook to transmute the language and principles of that science into English for the benefit of his countrymen. In this attempt he succeeded so well that his "Introduction to Botany," which was first published in 1760, has since extended to the eighth edition, and has greatly contributed to the progress of the Linnæan principles of botany among all who were unable to have recourse to the original. This work indeed gave Mr. Lee a priority in his time that rendered his garden, or as it was called, his Vineyard, the resort of all persons curious in botanical researches, and

added not a little both to his fame and emolument. As he had himself a true relish for his great object, the cultivation of curious exotics, so he was remarkably successful in the pursuit of it; and received with pleasure the visits of all who, like himself, felt the satisfaction arising from those pursuits, especially those who joined to their taste a scientific knowledge of their object. In what estimation he was held by the most eminent botanists of the age is manifest by the compliment paid him by Van Royen, the professor of botany at Leyden, who, in the year 1767, called a new genus—Leea—of the Monocotyledonous class after his name. Mr. Lee's taste was not confined to botany; he was greatly conversant with shells, insects, and fossils, in which branches he made very considerable collections. In the two former of these he was particularly assisted by his much-lamented daughter Miss Annie Lee, whom he had inspired with a love of his own pursuits, and who added to her intimate knowledge of them an exquisite taste in drawing both plants, shells, and insects.

To these attainments, which gained him the respect and esteem of scientific men, we must add that as a member of society he was distinguished for a mind replete with benevolence, in his friendships he was steady and warm, in his dealings he manifested the greatest punctuality and integrity, and he lived to reap the reward naturally consequent on such qualities in the accumulation of a comfortable independence. In his domestic connections he was a kind husband and tender parent, and had the satisfaction of experiencing the reward of such virtues in the dutiful dispositions and good inclinations of his family. He had the affliction late in life of surviving his daughter above mentioned, on whom he doted. He left a son, successor to the Vineyard.

He was for some time under Philip Miller at the Chelsea Garden, and afterwards gardener to the Duke of Argyll at Whitton, Middlesex, who was a great importer of exotic trees, and for that reason only invidiously nicknamed by Walpole "a tree-monger." In conjunction with Kennedy, then gardener to Lord Bolton at Chiswick, Lee commenced the business of a nurseryman at the Vineyard, Hammermith. He was patronised by a great many of the nobility and gentry, to whom he became known by his extensive knowledge of natural history; and his garden became particularly rich in plants from the extensive correspondence he kept up with Linnæus and other contemporary botanists. He died August 25th, 1795. He was author of—1, An Introduction to Botany, con-

taining an explanation of the theory of the science, and an interpretation of its technical terms, extracted from the works of Linnæus, &c., twelve plates, 1760, 8vo. A work which Pulteney speaks favourably of, as having tended to a general diffusion of a knowledge of the Linnæan system. 2, Catalogue of plants and seeds sold by Kennedy & Lee.

The business at Hammermith has been conducted by three generations of the family of Lee, and the latest partner in the firm represents the fourth generation. By the recent retirement of Mr. John Lee, after fifty-six years of hard and honourable work, his nephew has become a partner, and the firm is now known as Charles Lee & Son.

The business of the firm is extensive, and occupies four distinct grounds—at Hammermith, Isleworth, Feltham, and Ealing. The grounds at HAMMERSMITH have been considerably encroached upon by buildings and an important line of railway. Only a few trees are now grown at the "head quarters;" but there is a considerable amount of glass, with offices and packing sheds, for the management of the decorative plant and seed departments. Vines are also grown here, or the Royal Vineyard Nursery would otherwise be an anomaly. For these large light houses of modern construction have been erected, and prominent attention is given to the cultivation of Vines in pots. Other houses are devoted to the cultivation of plants. There are structures for Camellias, Azaleas, Palms, Orchids, and general decorative plants. The plants are better than the houses, but the latter will be eventually replaced by new structures erected on the most approved principles, and the "old place is to be made new again."

ISLEWORTH.—This is the propagating department for Conifers, evergreens, and decorative shrubs. The nursery is easily reached by train from Hammermith (Addison Road station, Kensington), and is well worthy of a visit. It is compact, clean, orderly, and well managed by Mr. Marsden. There are long ranges of propagating houses, in which Conifers are being struck by thousands, a series of nursery beds containing the young stock, and an open space of

ground where they are subsequently grown to a saleable size. Wood Lane, Isleworth, is in fact the nursery of the other nurseries—the manufactory, and the plants and shrubs are great in numbers, small in size, and choice in quality. The variegated-foliaged Japanese shrubs are extensively grown, the Eucyonemes alone numbering many thousands, to meet the great demand for these popular shrubs. They are all small, not having time to grow large before they are purchased. Eleganses and Ligustrums are also in great demand for town decoration, and are largely increased. Large stocks are also being provided of such choice Conifers as *Cryptomeria spiralis* falcata, *Abies excelsa* aurea (the Golden Spruce), *Juniperus* atica, glaucous, very distinct; *virginiana elegans* (Lee), neoboriensis, bright green and elegant, and several others. *Thuja Veranensis* is in great demand for winter bedding, as also apparently is *T. semper-aurea*. *Taxus gracilis pendula*, a distinct Yew, is noticeable, as also are *Cupressus Lawsoniana lutea* and *C. L. delicatissima*. There is also a choice collection of Ivies, and these, with some of the Japanese shrubs trained on low walls, produce an excellent effect. In this nursery Van Geert's Golden Poplar is a valuable acquisition.

A short distance from this nursery is the arboretum under the management of Mr. Webb. There several acres of ground are entirely occupied with ornamental deciduous trees. As affording an idea of the completeness of this department, it may be noted that the collection of Oaks alone includes nearly two hundred species and varieties. There are also a great

FIG. 3.—JAMES LEE.

variety of weeping trees, one even in its leafless state being very conspicuous—the golden-twigged Ash, the drooping shoots being of a bright yellow colour. There are many fine standards of Caraganas, Catalpas, and Genista prostrata, the latter being very novel, and when in flower brilliant. Gooseberries are also propagated in this nursery. This large and choice collection of deciduous trees requires to be seen in summer, and cannot fail then to repay anyone visiting it.

FELTHAM.—This nursery is a short distance from Honeflow. It is nine or ten acres in extent, and is occupied with Conifers and evergreens, from small plants to handsomely furnished specimens. Especially fine are the variegated Hollies. Yews are of almost all sizes, and in many shapes, some as flat as tables, others vase-shaped, some trained as pyramids, others as standards. Rhododendrons thrive here admirably, as also do Azaleas and other American plants. Wellingtonias, Deodars, and Pinuses are largely grown. Picea amabilis (tree) being exceedingly fine. Here the Golden Spruce shows its character, the upper surface of every spray being gilded as if with a brilliant ray of sunshine, the under surfaces being green. Here, too, is flowering the old and valuable hardy Heath, Erica codonodes. This is a real winter-flowering plant. It is of close upright growth, showing its thousands of white roset-tinted flowers to great advantage. It is likely to be in great request for winter bedding when its merits become known. It is being propagated by thousands. Not far distant from this nursery another plot of fifteen acres has been secured, and is being stocked with trees and shrubs. The Feltham Nursery is managed by Mr. Dixon, and it is only just to say that it does him much credit.

ELALING.—This is four or five miles distant from Houslow, and is convenient of access from the Great Western Railway. The soil is a rich tenacious loam, admirably suited for the growth of fruit trees and Roses, to which twenty-five acres of ground are devoted. The Roses have nearly all gone, but the few hundreds left tell of their robust character. The fruit trees, too, are as good as trees can be—clean, healthy, and well furnished. There are trees to suit all tastes—pyramids, standards, espaliers, cordons, and on stocks which experience has proved the most suitable for the several varieties. The Apples number about four hundred varieties, and one more useful sort has just been negotiated for—the true Russian Transparent. Pears are similarly numerous, and the collection of all other hardy fruits, trained and untrained, are very complete. There is a large house for the cultivation of Peaches and Nectarines in pots, and the stock of these trees is excellent. This nursery is in charge of Mr. Cannon. Such is an outline of this old and extensive business, which throughout a period of upwards of a century was never in higher repute than now.

CULTURE OF THE CYCLAMEN.

Of all winter and spring-flowering plants none have risen to so much repute during late years as the Cyclamen persicum, for its blooming period may be prolonged from the latter end of October until the latter end of April. Most growers sow the seed when it is ripe, and others not until the latter end of January. But it is always preferable to sow the seed in August, as then the plants have a longer growing period and will make larger plants. If sown in August the plants must be kept growing in an intermediate house close to the glass during the winter, and be grown cool in the summer. Seedlings always bloom the earliest in the season, and old plants later on.

The seed may be now sown in pans in equal parts of loam and leaf soil and placed on a hotbed, where the seeds will soon germinate. After the second leaves of the young plants are discernible prick the seedlings out into pans in the same kind of compost as the seed was sown in, and place them back on the hotbed close to the glass; it is not advisable to place the bulbs under the soil at this shift. After the plants have made a few leaves repot them into small 60's in a mixture of two parts yellow loam, one part cow dung, and one part leaf soil, with a sprinkling of river sand, and if convenient place them in a pit where there is a cool bottom and a temperature of about 65°. They must be repotted into 48's about the middle of June, keeping the bulbs well up to prevent the water from settling in the crowns. Sprinkle overhead on fine days and shade from bright sunshine. By the middle of August discontinue sprinkling overhead and give an abundance of air night and day; a little manure water at this stage will be beneficial. It will be better for the plants if they are now

placed on a stage so as to have a free circulation of air among them, for they dislike damp. If they have been attended to as herein directed they will commence blooming by the latter end of October.

After they have done blooming give enough water to keep the leaves from flagging, and place them in a dry and well-aired situation under glass. The best time to repot them is when they begin making fresh growth. It is best to grow the old plants under cool treatment, keeping them well ventilated. —A. Y.

FORETHOUGHT REQUIRED IN GARDENING MATTERS.

PERHAPS there is no occupation that calls for more forethought than that of the gardener in a responsible position, for not only has he to tax his brain with what is likely to be the wants of the family he serves during the current or coming year, but he has to cast his mind still further ahead, and propagate or prepare fruit trees and shrubs which may be wanted years hence. Besides fruit trees and shrubs other crops, such as Asparagus, Sea-kale, Strawberries, &c., require his attention; for although these last several years, yet nevertheless they have a period of usefulness allotted them, after which they are no longer profitable, but must be succeeded by others, which it becomes the prudent manager to provide in time equally as much as the requisite number of bedding plants are by those whose study is to make the best display possible in their flower beds. Now to do all this effectually is no slight tax on the thinking powers of the person in charge, because, apart from what is the ordinary routine—the regular work—there may be much extra work in some department or other. The pleasure ground may be enlarged, or new walks or drives formed which it may be advisable to embellish with shrubs, and if a quantity can be brought forward in readiness for such alterations the advantage will be great. It is better to have plenty of small shrubs rather than a few very large specimens. Nothing tends to enliven a walk or drive through a copse or wood of deciduous trees so much as a plentiful sprinkling of evergreen shrubs, and it often happens that there is room for improvement to be made this way in the most complete places so called. At the time when old walks or drives were formed choice flowering shrubs or evergreens were possibly not so plentiful as now, so that we must not scuse those who made these drives, &c., of lacking liberality or knowledge of such matters, but simply the means were not at hand; whereas now-a-days nurseries are scattered all over the country, and choice shrubs, &c., exist in countless profusion, and are to be met with at a reasonable rate—very reasonable indeed in many cases, and the experience of the last few years has pointed out how important a part these are capable of playing in decorating private drives and public places. Even some of the wastes that have been taken in near large towns, which though formerly producing only weeds and Gorse, now glitter with Rhododendrons and other shrubs, to the delight of all who look at them. Hollies also are equally beautiful in their way, and where they exist as an undergrowth in some well-managed woods nothing possible can look better; but they are nevertheless not the easiest shrubs by any means to transplant and do well, and it will often be found that the place where they exist in the greatest perfection is where they have been planted by Dame Nature. But where the soil is suitable other shrubs also seem capable of being naturalised. The broad-leaved Berry, or Mahonia as it is more properly called, will sow and propagate itself where the soil and situation favours its doing so; and I believe the same is the case with B. Darwinii, which is still more beautiful. But the shrub of all shrubs for decorating some dry-looking sterile waste is the Rhododendron. This beautiful evergreen is now making its way over moors and common, and into plantations of all kinds, being often planted extensively for game cover, and is not injured so much as most other shrubs by that pest of all kinds of vegetation the rabbit; but to say that it is never attacked by these vermin is saying too much, for I have known thousands of Rhododendrons destroyed by rabbits, perhaps not eaten or partook of as food, but bit off as they grew. I may further add that rabbits have a particular relish for the choicest varieties. I do not know how to attribute this, but I suppose it is from that inherent instinct they have for mischief-making they choose the best.

Examples of the accommodating capacity of the Rhododendron to various situations are numerous. I need only call

attention to the display which these have made in places where the spirited liberality of those who planted them extensively in time long since gone by. Foremost amongst such places is Cobham Hall in Kent, where a former Lord Darney planted them on a hill intersected by walks or drives with overhanging Birch trees. Now these Rhododendrons have self-sown themselves all over the ground, that they form the principal crop, and flower in the greatest profusion at the proper time. Equally abundant, or perhaps more so, are they to be met with at Heron Court in Hampshire, the seat of Lord Malmesbury, where they are found growing by hundreds in the woods, and in some cases hanging over into the public roads, offering their tempting trusses of bloom to every passer-by. There is a little difference, I believe, in the appearance of the soil at the latter place to that of Cobham, but both contain all that is essential to the well-being of this plant, and to those who have seen it growing in profusion at places like those referred to, cannot fail to be highly pleased with it. To the sportsman it is also, perhaps, one of the most agreeable of all covers for game, and is more pleasant to pass through than Bramble or Gorse, or the mixed Beech coppices of ordinary undergrowth. It is on this account alone that the Rhododendron has been extensively planted of late years; and to all who have a wood occupying a dry elevated site, and a soil that seems at all adapted for it, I would advise a trial of these evergreens to be made—say a few groups of a few plants together first and wait a year or two, and if they succeed then more extensive planting can be carried out. Furthermore, I would advise those who do not wish at once to embark in a costly plantation, to look round and see if a suitable site for a piece of nursery ground can be had not too far from where the ultimate plantation is to be, and if it is in a wood to trench and prepare it, and after obtaining a few thousands of young seedling plants from some nurserymen who supply such at a very low rate, to plant them out in this nursery for two or three years, when they will take-up with balls as large as you like, and can be easily removed to their final quarters and planted, and being to a certain extent acclimatised to the soil, and they will do better than those imported from a distance of the same size. To do all this requires an exercise of that forethought to which this chapter is mainly directed. I ought not to leave the subject of the Rhododendron nursery without remarking, that if it be situated in some wood or other place where rabbits abound in great numbers, it ought to have a rabbit-proof fence around it, otherwise it will be found that these vermin will destroy a great number of the plants.

It will easily be seen that many other shrubs may be propagated or reared as well as the Rhododendron where planting is contemplated. The berries of the Aucuba may be sown and young plants raised, a due proportion of which will probably be males, and when planted along with the other kind a bountiful crop of berries will be produced without any artificial help whatever; and it is possible hereafter, when the plants become more numerous and are planted extensively in places where they thrive, that they may eventually sow and propagate themselves in the same manner as the Holly and Rhododendron does. A suitable site and soil will no doubt enable many other shrubs to fit themselves to the neighbourhood. For instance, Privet multiplies itself in a general way to any extent, and in some places Spurge Laurel (*Daphne laureola*) does so too, while more often the Butcher's Broom is found growing wild in great abundance. Less plentifully is also the Juniper and Box, and in a few localities the stately and dignified Yew is similarly met with; but as all these are British plants they may very properly be expected to flourish. There seems no reason why many other hardy shrubs should not assimilate themselves to the position in this country resembling those from whence they came, that future generations may possibly look on many of them in the same light we look on the Rhododendron, as useful accessions to our woodland scenery, and reflecting great credit on those who first placed them where they all that time appear to so much advantage.

Having diverged on the culture of the Rhododendron, I must leave the further consideration of the subject of looking forward to the wants of a future time until another occasion, unless someone else supplement what has been already said by pointing out new directions in which forethought ought to be directed, as the matter is one on which a good deal may be said, and it is also one to which we cannot too forcibly call the attention of all concerned. By a judicious timing of things in general present work need not be neglected, the great secret being to do everything at the most expedient time,

the study of which alone forms one of the features of that prudent forethought which it is so desirable to direct and encourage.—J. ROUSON.

CULTIVATION OF THE RASPBERRY.

The Raspberry is not so much valued for dessert as some other fruits, but for preserving, and especially for making vinegar, it is greatly esteemed. Amateurs with small gardens generally grow a few rows of canes, and in large gardens extensive quarters or plots of ground are devoted to Raspberry culture. In many parts of England and Scotland it grows wild in the woods in large quantities. The fruit on these, however, is not so fine as when the plants are properly cultivated, and any attention they receive in this way is always amply compensated for by the extra size and abundance of the fruit.

Young plants are sometimes raised from seed, which is sown in well-prepared soil about this time; but this mode of increase has so little to recommend it that I will make no further remark concerning it, but pass on to say that the best way of propagating the Raspberry, and that generally adopted, is by suckers or offsets. These may be taken at any time during the period the leaves are off the canes. In severing them a spade should be used to cut the roots clean away from the old plants, and in doing this care must be taken not to injure the roots of the latter. Old plantations generally throw out suckers some feet from the base of the canes or roots which were originally planted, so that from such plenty of suckers can always be had without much danger of doing damage in any form. Perhaps I shall be better understood in the following way: Supposing a few rows, or any extent, of canes to have been planted six or more years ago, the roots by this time will be very large, with many ends of old canes projecting above the soil. The young canes, especially if the plants have been the least neglected, will not be so strong as they were for a few years after they were planted. This indicates a decline in the plant, and when this takes place it is always much better to make a fresh plantation than spend time in trying to uphold the vigour of the old plants. But the old plants should not be discarded until others have been provided to take their place, and to do this the suckers must be taken off at least one year before the old plants are thrown away.

Plants in a degenerated state at present should have every sucker taken from them at once; but previous to doing this dig and abundantly manure a piece of ground, and the suckers must be planted in this in rows about 18 inches apart. Here during the summer they will make strong canes, and what is of more importance at this time, a mass of strong roots. Early in autumn the strongest piece of ground in the garden should be cleared of its occupants, a quantity of manure spread on it, and then be trenched and mixed to the depth of 2½ feet. Planting may then be proceeded with, the young canes being taken from where they have been growing throughout the summer, and planted 5 feet between the rows and 1 foot between the plants. If planted in this form they have to be trained to a trellis. This is made by placing strong upright supports 8 or 10 feet apart, and nailing two or three narrow strips of wood to them, to which the canes must be tied. This support should be 4 feet high. In the place of the narrow strips wires may be fixed, and when this is done there must be a strong support at each end of the row to keep the wires tight. Another plan is to plant a root every 2 or 3 feet, and train the canes from it to a straight stake, but this plan and one or two others which I have tried I have not found so profitable as the first described. However, whichever way of training is adopted, the supports should always be fixed before the young roots are planted, then plant the roots to them. After planting tie the canes to the supports, and nothing more will require to be done until the following autumn excepting frequently Dutch-hoeing the surface about the roots and between the rows. Let all the young canes grow which appear. Little or no fruit will be had from them during the first summer they are in their permanent quarters. At the end of the first season after planting loosen-down the old canes and cut them away level with the ground, then select three or four of the strongest canes made during the season and tie them in the place of those cut out. The strong canes may be topped at 4 feet from the ground, the weaker at 2 feet. Do not tie them closer than 3 inches apart against the trellis. When tied to stakes it is difficult to avoid crowding, and this should be avoided when well-developed fruit is desired.

Pruning and training throughout their existence consists of

an annual repetition of this practice. After pruning a good quantity of decayed manure should be spread over the roots and turned in about 2 inches below the surface of the soil with a fork. Do not turn up any of the roots in doing this; some only spread the manure over the surface, and do not cover it with soil, but this is the least profitable way, although it is rightly supposed that part of the nutriment from the manure is washed down to the roots. Plenty of good feeding at the roots is excellent at all times for the Raspberry, and this must not be neglected or failure will be the result. When in a healthy free-growing state insects or disease of any kind is never troublesome.

The following varieties are worth growing:—Carter's Prolific, very large red; Red Antwerp; Fastolf, dark red, great bearer; Fillbasket, prolific and excellent; and Yellow Globe, pale yellow with fine flavour.—PRACTITIONER.

CATALOGUES.

ALTHOUGH an amateur my address appears to be known to most nurserymen, seedsmen, and florists, for a pile of catalogues are already to hand. I shall select from time to time something from most of them, and they will be also kept for reference—at least such of them as can be conveniently referred to—and this brings me to what I have to say.

An eminent horticulturist remarked to me the other day that a catalogue should possess two essentials—accuracy and convenience of arrangement—should be, in fact, like a dictionary, where the representatives of any known genus, at least those of current value, should be alphabetically arranged, enabling them to be turned to at once. I am quite sure that that is a right view to take of catalogues, and it becomes the more necessary to adhere to it since these compilations have become so voluminous. I willingly admit that many catalogues are admirably "turned out," and far surpass in excellence of execution the trade lists of any other country that I am acquainted with, but the English do not surpass the foreign catalogues in accuracy.

A catalogue of plants and seeds, but especially of the former, should be copious yet concise, and if the contents are not alphabetically arranged a full index becomes a necessity. Yet there are some catalogues which are bulky in their nature and arranged in sections, but are without even a sectional index. For myself I never refer to such lists. I cannot spend half an hour in searching for that which ought to be found in a few minutes. A catalogue should be a guide and not a puzzle.

I recently had occasion to consult some lists of popular plants, such as florists' flowers and bedding plants. I laid my hand on a "guide" which I considered would contain precisely what I wanted, so perhaps it did, for it was very comprehensive but so divided into sections, sub-sections, and minute "classifications" that the work of wading through it became positively irksome. I submitted this "guide" to an author (above alluded to) of standard horticultural works, who after a careful perusal of it returned it with the remark—"It is one of the best and one of the worst catalogues that I have seen." I quite feel that he was justified in that remark, for the lists of plants are extremely ample but most perplexingly arranged.

I am glad to see that the names of the raisers are being attached to meritorious flowers. That is an act of justice to the men, and renders a list additionally instructive and less liable to be thrown aside as ephemeral. The good old plan of placing the raisers' names in parenthesis in an alphabetical list of the names of flowers has not yet been improved upon, and catalogues thus arranged are the most generally acceptable.

The descriptions attached to many plants and flowers are frequently unnecessarily prolix. I do not mean the scientific descriptions, but the details of the merits and qualities of the plants described. There is too much repetition, too many sentences of praise, as if each was a prop for the other, strengthening it. It is not so. Many props are suggestive of weakness, and mixing is generally diluting. A clear, terse, firmly written sentence in one line is worth a dozen lines of laboured eulogium.

It is common to hear the opinion expressed that catalogues are growing unwieldy in size. I think there is force in that remark, and from this fact—I have two or three excellent examples of modern catalogues; so attractive are they that I could wish that many of my amateur friends could see them, friends who have gardens but who know nothing of the existence of these elaborate garden annuals. It is only my nearest neighbours to whom I can conveniently show these "volumes,"

but were they of a size to fit my breast pocket or even my "black bag" without being crushed and injured, I am confident they would be "handed about" much more extensively than they now are.

A word cannot be withheld on the pictorial aspect of catalogues. The illustrations are more chaste than before, and more truthful. There is less of the "Little-Red-Riding-hood" character about them than formerly, when they were suggestive that horticultural readers were as children, requiring "plenty of colour" to catch the eye and amuse. A first-rate plain engraving leaves a much better and more lasting impression than does a fifth-rate coloured picture, and not one in a hundred of these are of more than that calibre. In this respect the preparers of catalogues have shown excellent taste in giving a few good coloured impressions rather than a plethora of cheap "Red Ridinghoods." As I can hand my catalogues to but few friends I can only advise other amateurs to purchase, for the catalogues are "marvels of cheapness" at their advertised prices, and they are highly calculated to foster a taste for flowers and increase the interest in gardening which is so desirable and beneficial.—AMATEUR, F.R.H.S.

HYDRANGEA HORTENSIA OR HORTENSIS.

THE common garden Hydrangea is called *H. hortensis*, a very common error. Knowing it to be named *H. Hortensia* in honour of some French Madame Hortense, I wrote it "Queen Hortense," without stopping to consult the authorities, as I should have done had I supposed that the note would be printed. I was wrong as to the particular Hortense, but right as to the point I wished to make—that *Hortensia* is the proper specific name of the plant, and that *hortensis* is wrong.

The botanical name of the plant is *Hydrangea Hortensia*. The reason for giving this name is told by several authors, but the story is nowhere more concisely related than in London's "Arboretum et Fruticetum," vol. ii., page 996. After giving the names for the plant in Chinese and Japanese, London says:—"In Europe it was named by the celebrated Comtesse in honour of Madame Hortense Lapante, wife of his most particular friend, M. Lapante, a watchmaker. Comtesse first named it *Lapantia*, but in order that the compliment to Madame Lapante might be the more direct, he changed the name to that of *Hortensia*, from her Christian name, *Hortense*. The plant was afterwards discovered to be a species of *Hydrangea*, a genus previously established by Gronovius; but the name *Hortensia* was retained as its specific appellation, and it is still the common name by which the plant is known in French gardens."—(*American Gardeners' Monthly*.)

CLIVE HOUSE SEEDLING GRAPE.

THE notice of this seedling by Mr. Bowie in your last issue requires a few plain words.

First, as to the implied charge of claiming to have raised the seedling myself. I have to say that I did not exhibit it as my own raising. This condition was not required by the Committee, nor was it demanded in the interest of horticulture. It is sufficient that the variety be new, distinct, and of superior merit.

Second, as to the actual history of the seedling. That given by Mr. Bowie, that it was raised by Mr. Wm. Caseley twenty years ago, is absolutely and demonstrably wrong. The Vine from which my specimen is believed to have been taken was raised by Mr. Bailey, late gardener to the Duke of Northumberland, at Stanwick upwards of twenty years ago, and brought by him to Alnwick along with several other seedlings. Two of these are now preserved in the Castle Gardens, and have all along been known and shown as Bailey's seedlings. I received mine six years ago; it was given, and was labelled as Lady Downe's. On being fruited the difference was obvious to myself, to Mr. Ingram the present head gardener at the Castle Gardens, and others, and it was supposed to be, and has been freely spoken of, as one of Bailey's seedlings ever since. No story of Mr. Caseley having raised it has been given out till the past summer, when its superiority became manifest. The story of Mr. Caseley having raised it was then and there flatly contradicted in the presence of a noted Grape-grower. So far as I know and can discover, no seedling Vine other than those brought by Mr. Bailey has been raised or fruited at Alnwick Castle Gardens since Mr. Bailey came, upwards of twenty years ago.

Third, as to my right to the seedling. On discovering its

value I saw Mr. Bailey, whom I had not seen since he left Alwrick, and obtained his unqualified sanction to offer it and do with it as I liked.

Fourth, as to its identity with the seedlings now at Alwrick Castle Gardens. I do not vouch for such identity. There were several brought by Mr. Bailey. Whether the one from which mine was taken has been preserved, or whether mine was raised from one of those destroyed, I am not called on to affirm or deny. This, however, I know, that an attempt was made three or four years ago to obtain a certificate for one of these very seedlings which signally failed, whereas on the 6th of December last my Grape at once and unanimously obtained a first-class certificate.

Fifth, as to the name. It was necessary to give one before the certificate could be issued, and in the circumstances as above narrated, I had no scruple in giving its present name, "Clive House Seedling," as Mr. Bailey the only other party to be consulted, had given me full liberty to do as I liked.

The Vine thus named and registered must stand on its own merits. After all has been said it is a founding the parentage and connections of which none can vouch, but its high qualities have secured it the unanimous approval of the Fruit Committee of the Royal Horticultural Society.—D. P. BELL.

DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

KITCHEN GARDEN.

We have still been debarred from doing any work on the kitchen-garden quarters owing to the wet. Peas that were sown on a border facing south about the end of November are making very fine growth. We shall always when sowing early dress the seed with the carbolic mixture recently alluded to, as it most effectually protects the Peas from mice. The same mixture is equally valuable for dressing seed Wheat, and prevents it from being eaten by the rooks: a pint and a half of the mixture is sufficient to dress thoroughly four bushels of Wheat. This ought to be good news for farmers who have to pay a boy to drive away the rooks, which nevertheless generally contrive to carry away a large quantity of the precious grain.

The Peas sown to stand the winter were William I., Alpha, and Dr. Hogg. Our experience is that the first-named is an excellent early variety for standing the winter; it is also very early, and altogether is perhaps the best garden Pea for the earliest crop. The pods when ready for gathering are very large and of a dark green colour. Alpha is not such a hardy variety, but it has stood bravely through the wet and the damp, muggy atmosphere. It is a wrinkled Marrow, not perhaps of the quality of Veitch's Perfection or No Plus Ultra, but it comes nearest to them, and is only a week later than William I. The pods are not so showy nor of such a dark glaucous green as William I., and for that reason are not so well adapted for exhibition, but it is quite certain that the Alpha will always be preferred when cooked. The true stock of Dr. Hogg is a grand early and prolific Pea, but it is a question whether the true stock has not in some way become mixed with a spurious variety. The seeds of the right variety are wrinkled and slightly angular. It is the best variety to succeed Alpha. We cleared some Broccoli from a dry border, forked over the ground, and made another sowing of the same varieties.

For later sowings we might trust to varieties raised by Mr. Linton, as such sorts as Hill-top produce enormously, but our last year's experience with Dr. McLean will lead us to sow large quantities of that sort. If we are not mistaken it will hold a high position in years to come. Veitch's Perfection also must hold a place in every collection. In our dry soil with ordinary treatment the Pea crop is apt to fail at the height of the season; but when the ground is trenched and manured as advised in previous numbers the Peas usually bear heavily and continuously, but the pods must be gathered as soon as they are ready. Allowing the pods to become over-ripe is fatal to a succession of them.

Celery has not suffered from frost this winter, and clean straw placed over the ridges as recommended in the autumn throws the wet from the top of the plant; it is, of course, carried down between the ridges, but there it can do no harm. We looked over the Potatoes intended for planting. They have been kept in a dark place and have sprouted to a considerable extent. These sprouts were rubbed off, and the sets were laid in shallow boxes in single layers; a little earth was placed around them—just enough to show one side of the Potato above the soil. The best place for the boxes is then to place them in a cool greenhouse, any tight place where the growths will be strong and healthy. Of course frost must not reach them.

We have left Jerusalem Artichokes in the ground, and dig them out as wanted. A quantity of Horseradish was trenched up and stored, and some more planted for use in future years.

VINERIES.

All who make any pretence to grow forced Grapes will by this time have started their early Vines. The Vines in our two earliest houses though pruned early cannot be said to be starting well. The growths are breaking very regularly over the canes, but they do not possess that vigour which so delights the Grape cultivator; still they are likely to start freely when the continued heavy cloudy atmosphere gives place to days of occasional sunshine. Since the Vines were started, one house in November and the other early in December, we have had probably but one day in which the sun had sufficient effect to raise the temperature to the maximum point. This, to some extent, will account for the slow progress the growths have made. There still seems to be considerable difference of opinion as to the desirability of applying bottom heat to early vinery borders. It has been stated, and it should be a warning to others, that placing fermenting material on the borders about two months before starting the Vines is likely to cause complete failure. It does not seem reasonable treatment to do this, but many gardeners fancy that it is wise to start the roots before the tops. Our own practice, which has always been successful, is to water the borders outside and inside with tepid water, and as the water is applied the fermenting material is laid on to keep the heat in. The same day that this is done the house is started with the temperatures which were recorded at the time. As soon as the buds have started an inch or so, the fermenting material, which has lost most of its heat, is turned over, and some fresh added to it. During the operation more water is applied. This is repeated four or five times during the season. The last watering takes place when the Grapes begin colouring. We do not always cover the inside borders, but a narrow ridge of fresh stable manure is placed in the house, and the heat is kept up by frequent additions from the stable. Until the Vines start into growth the canes are syringed with warmish water once or twice a day, afterwards syringing is discontinued.

Vines in pots should be kept in rapid growth. The night temperature ought not to exceed or fall much below 65°; in mild weather it may rise to 70°. Bottom heat for the pots ought not to fluctuate much from 85°; the pots should not be plunged to the rim, two-thirds of their depth is better. After the fruit is set dressings of rich manure act beneficially; they entice the roots to the surface, and they work into the dressing.

GREENHOUSE AND CONSERVATORY.

Those who grow specimen hard-wooded plants will now be able to find time to tie the flowering wood into position. This work requires that the operator should have a knowledge of the plant upon which he is engaged. Not a flower show is held during the summer months but numbers of plants may be seen tied in a manner that they would not have grown into naturally. Severe and formal training must also be deprecated as an outrage on good taste; all the flowers and growths are trained into a position that does not admit of the slightest irregularity of outline; if a flowering growth should escape a few inches out of its place it is trained back to preserve the regularity of surface. The experienced exhibitors—those who have gained a high position in plant culture—will not outrage good taste in this matter of training, and judges who are well up in their work will surely take into consideration the method of training as well as the health and other points of culture in the plants.

In reference to the arrangement of plants in the conservatory or greenhouse it is not the merits of this or that plant that are taken into consideration, but the effect of the arrangement as a whole; still to a cultivated mind well-grown healthy plants, each one trained into a pleasing position, will be the eye, yet the eye is not the first object and not the training of it is of paramount importance. Such plants will look well on any stage, and will also form a perfect and harmonious whole. They ought not to be placed closely together, nor will they require to be. Not unfrequently plants are placed thickly together either to hide unhealthy or badly trained specimens, and the mere fact of placing them thickly together for this purpose tends to make matters worse, as badly grown examples will become worse, and those which are unhealthy will die outright. Any plant in good health freely exposed to light and air will have a tendency to grow in its natural position, and should be trained accordingly.

At this time great care should be taken in watering, but nearly all plants require more water now than they did a month ago. Heaths, Azaleas, and most of the New Zealand plants are now making roots, and some of them are beginning to make growth, and at the same time to suffer for want of water would injure them for the season; the small hair-like roots are killed, the energies of the plants are crippled, diseases and insect pests are also encouraged by injudicious waterings.

Hyacinths, Tulips, forced shrubs, Roses, and other plants are now being brought in, and they must also be kept in health. The greenhouse or conservatory should be kept a little closer for a day or two after a batch of newly-forced subjects are introduced. As plants go out of flower they must be removed to some house where they will restore their wood for next season. It is ruinous even to hardy plants to place them out of door

after they have been forced; the young growths, if they are not killed, certainly suffer material injury by that violent exposure.

FLOWER GARDEN.

We are now about making preparations to propagate such bedding plants as are best propagated in the spring, or of which there is not sufficient stock. We prefer a heated pit to ordinary box lights. The temperature of the pit is kept at about 55°, and a bed is made up of any fermenting material that can be obtained, some cocoa-nut fibre refuse being placed over the surface of the bed, in which to plunge the pots. It is difficult in our district to obtain healthy cuttings in the autumn, and they do not improve much in health during the winter. The best treatment is to place the plants in heat about Christmas to promote growth, and as soon as cuttings can be obtained they may be taken off and propagated, and with a little care a fine healthy stock can be obtained; red spider, thrips, and green fly must not effect a lodgment upon them. Ageratums, Heliotropes, and indeed all free-growing plants make the most healthy stock if propagated in spring. All sorts of Pelargoniums ought to be propagated in autumn.

In the florist department there is always plenty of work after this time. Auriculas, if the weather is open, may be surface-dressed after some of the old surface soil has been removed. The plants must be freely ventilated when the weather is mild. In fine open weather the lights should be removed. It is a subject of some anxiety as to how Auriculas will flower next season, as they have not had the usual resting period. The soil has scarcely ever been frozen in the pots. Carnations and Picotees are in a similar plight; the growth is suggestive of March more than of January. We keep the pots clear of weeds, water with caution, and air freely.

Tulips are fairly out of the ground, and growing apace. They must be protected in some way from severe frost, and should the weather be for a few days, stirring the surface of the beds will be of much advantage to them. Pinks require similar treatment. If the surface of the ground is just stirred it dries rapidly.—J. DOUGLAS.

TRADE CATALOGUES RECEIVED.

James Veitch & Sons, Royal Exotic Nursery, Chelsea, S.W.—*Catalogue of Garden and Flower Seeds, Horticultural Implements, Knives, &c.*

B. S. Williams, Victoria and Paradise Nurseries, Upper Holloway, London, N.—*Catalogue of Flower, Vegetable, and Agricultural Seeds, Garden Implements, &c.*

Thomas Buryard & Sons, Maidstone.—*Descriptive Catalogue of Vegetable, Flower, and Agricultural Seeds.*

Edmund Philip Dixon, 59 Queen Street, Hull.—*Descriptive Catalogues of Vegetable and Flower Seeds.*
Hooper & Co., Covent Garden, London.—*Illustrated Catalogue of Seeds and Garden Requisites.*

TO CORRESPONDENTS.

* * * All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

BOOKS (P. J. O. H.).—London's "Hortus Britannicus."

EPHYLLUMS AND PERESIA (A. B. G.).—They are closely allied to the Cactaceae. The genera were formerly combined. Any florist who advertises in our Journal could supply you.

ARNOTT'S STOVES.—"West Riding" wishes to know where these, suitable for a plant house, can be purchased.

AMATEUR'S WHEELBARROW (R. K.).—Write to the Rev. J. W. Huthwaite, Bawthorpe, Ebor.

STRAWBERRY AND HOP PLANTING (N. J. M.).—Strawberries may be planted whenever the soil is in a suitable condition. If planted from the present time onward to the spring, little if any good fruit would be had this year unless the plants were very strong and a year old. They will answer perfectly well in the ordinary soil of a good garden. Hops may be raised from seed sown in March, but the usual method is to plant "sets," consisting of that upper portion of the roots which all good cultivators cut off at this season of the year. The culture of this plant is so simple that it will suffice for all ornamental purposes to plant it in good soil, training the growth upon poles or such other supports as fancy may suggest, keeping the foliage quite clean, and removing the growth after it decays by cutting it off close to the ground.

MELONS DISEASED (Eyre Court).—The specks upon the fruit when approaching ripeness are a consequence of too much moisture both at the roots and in the atmosphere, the latter being not only moist but close. Keep dry when ripening, and avoid too rich soil; nothing answers so well for melons as strong loam, the top 3 or 4 inches of a garden, laid up with this soil in the first of the year, and the plants set in it. If the soil is too rich, the fruit is dead, though we have frequently used it fresh. Chop up rather fine and tread firmly in the bed, firm soil inducing short-jointed fruitful growth.

PROPAGATING BEGONIAS (E. W. B.).—All the Begonias may be propagated by cuttings, which is best done in early April—cuttings of 2 or 3 inches length inserted in sandy soil and placed in a hotbed, keeping close, moist, and shaded until root, the top 3 or 4 inches of cuttings may be taken off, the young shoots when they can be obtained and struck in gentle heat. They

will grow on and form bulbs. Plants are also readily raised from seed, which may be sown in March in a hotbed. The large-leaved variegated section may be raised from leaves, pegging them upon the surface of a pot and keeping moist; young plants will arise from the midribs of the leaves, which should be detached and potted-off singly.

MEADOWS GROWING (St. Edmund).—The "small place" would give you very little room for a bed, as you would not be able to walk alongside the bed without taking up too much of the space. Either the coach-houses or stable would answer well, and preferably the former, as it is the freest from draught. No drainage is necessary; the bed may be made upon the hard floor.

PRODUCTIVE CUCUMBER (Idem).—Growing upon ten in frames and wishing to have a fresh one every day, there are two better than one of the Six-Node House type. MERRI'S Duke of Edinburgh is the best we have grown. Telegraph is a very good variety, better for houses than frames. The former will, we feel certain, satisfy you as to quality and quantity.

PRUNING NEWLY-PLANTED FRUIT TREES (J.).—The trees doubtless made a large quantity of fibrous roots last year, and will be in a condition both to mature fruit and make plenty of growth. We would not prune severely this year; cut back the points only of the young wood.

FERNS AND OTHER PLANTS DISEASED (G. M.C.).—They have been attacked by thrips and red spider. You must fumigate with tobacco smoke to destroy the first, and syringe the leaves freely for the spider. As the leaves are much affected it will be necessary to fumigate three or four times at intervals of three days.

JOINING HOT-WATER PIPES (D. H. W.).—Your plan of using iron filings and old rope is the best. If too much iron filings are used in proportion to the rope the joints are apt to crack. We have seen good joints made with gutta percha rings made to fit tightly into the socket. Red lead has also been used with success.

ORANGE GRAPTING (A Constant Reader).—The operation should be performed within 6 inches of the ground. In such a way trees will be produced having clean stems from 1 to 2 feet in height. The plants should be kept in a close frame or pit until the union has fairly taken place; and if the stock is slightly stimulated at the same time, by being plunged in a moderate bottom heat, the union will be more speedily accomplished. Any of the ordinary methods of grafting may be employed, the great object to be kept in view being to have the scion and stock of nearly the same size. No clay is used, but a little fine moss is placed over the point of union, and many only secure the scion to the stock with two or three rounds of soft woolen yarn.

MELONS FOR EARLY CROP (G. D., Beaumais).—You wish for four varieties. Read's Scarlet-flesh, Cox's Golden Gem, Easton Cash, and Meredith's Hybrid Cashmere are good and free sitters.

TROPEOLIDS (A. F. B.).—We think your Tropaeolum is *T. tuberosum*, and not *T. speciosum*. If you will send us a spray with flowers in the summer we will gladly give you the information you require.

FERNS UNHEALTHY (Stoke-on-Trent).—We do not think the large frond you have sent has been eaten by a caterpillar, but we rather attribute its decay to a close damp atmosphere, and the dripping of condensed moisture from a roof of the house. The frond has farther been infested with thrips. Sponge the plant with strong soapy water, and provide a more genial temperature—a less stagnant atmosphere. *Adiantum farleyense* frequently loses some of its interior fronds, their decay being accelerated by a low temperature. Remove all the decaying parts, top-dress the plant with fresh compost, water carefully, and raise the temperature of the house if below 40° at night.

INSECTS ON VINES (A. B.).—They are the thrips, and may be destroyed by fumigating with tobacco two nights following, and each morning, after the night's fumigating, syringing with water at 120° with 8 ozs. of soft soap and a pint of tobacco water in each gallon. Repeat the application at the end of three weeks.

NAMES OF PLANTS (G. P.).—We cannot name from leaves only.

POULTRY, BEE, AND PIGEON CHRONICLE.

LES BASSES-COURS D'ANGLETERRE.

CHAPTER XII.—BIBURY, FAIRFORD.

It certainly was bitterly cold that drive from Cirencester to Bibury, along rough country roads and over hills with no protection, in one of the coldest winds we ever felt. We missed our south country hedges, for those built-up walls of loose stones looked so cold and cheerless, but when we came to Bibury it seemed so far from the middle of a wilderness. Directly we passed the home of Mr. Dutton's "collaborateur" with the mouthy roses still blooming fresh and bright upon its walls the scene changed, and it seemed as if a "merceau" of a continental village had been bodily dug-up and planted in the middle of those dreary expanses of arable lands. The hill for a background was there with picturesque cottages nesting in nest gardens at its feet; the village mill, the flowing river with its colony of domesticated waterfowl, the village church, the village emporium, the bright village inn; all were there.

Well, we passed them all, and we came to the vicarage. This was in November. It is now January! We have in pet unscratched borders snowdrops, anemones, and aconites blooming to-day. We hope Mr. Dutton has, but we tremble for the chance in those borders opposite the porch, for in them we have Black Red Gem hens as Black Red Gem pullets dusting, bathing, scratching regardless of bulbs, and perfectly indifferent to the cats stretched over them. We clasped our hands while the servant was answering the bell, and in a moment the fowls were up and scudded away amidst the thick shrubs, leaving behind only the faint recollection of some twenty or thirty birds well coloured, well shapen, and in hard feather.

Like many other Game-breeders Mr. Dutton keeps his cocks and cockerels at distant farm runs. We believe no less than sixteen homesteads in the neighbourhood afford country run and protection to small colonies of Black Reds, many of which, of course, are far away across those windy hills and engine-ploughed fields, and these we could not visit, but we made a good tour of the home premises and of many of the neighbouring farm runs. We do not profess to be Game judges, but in the company, as we were, of the owner of the birds and of the Stowmarket hero, who also was there and went round with us, we tried to improve our poultry education. We have repeatedly noticed that Game breeders have no fancy or regard for other varieties, while Cochins, Dorkings, or other breeders have greater knowledge of various breeds. We mean this as no personal insult to our many Game friends, but say it *en passant* rather as an excuse for ourselves. Well, to return: in the vicarage yard we saw large roomy wooden pens placed on tressles, and here were Black Red and Ducking cocks and cockerels penned for inspection and to get themselves accustomed to such confinement for the Palace and Birmingham tournaments. Good birds they were—some of the pick of the yards, looking invincible in their hard plumage and brilliant condition. We saw a very good cock, son of the Wolverhampton (1875) first bird, which lost his eye before he was shown, and he has since lost the other, and has consequently, we hear, been killed, but not, however, before he had bred some very stylish daughters, one or two more particularly so, by Mr. Matthew's old cup hen. Then we saw in a run near the church a singularly clear Silver Ducking cock; but this variety we hear Mr. Dutton intends to abandon, and so give more space for the Black Reds. Then next we saw at a barn the cockerel which most Game fanciers know, and which so many thought should have been first at Oxford. He was running with the hen which took the cup at the Alexandra Palace, and with her sister, who was much of the same stamp; and there were there, too, another promising cockerels, some not then in full feather. Then we saw a tribe of cockerels on a grass run above the kitchen garden, which have one of those charming old dovescotes to live in—one of those old manorial and substantial buildings belonging to bygone days. The lower nests had been removed and a ceiling put below the glazed lantern for the sake of warmth, and there on swinging roosts these cockerels slept.

Near here were some Indian Game—the genuine article, not the half-bred birds we see so many of the West of England shows. From a trio of birds which came to Mr. Dutton from Ramport only one bird (a hen) survived the journey, and she was put with a pure Montrose cock; but it was late in the season and only a few chicks hatched, which were late, but their owner hopes gradually to spread the genuine breed. We would advise him to try and obtain for them a class at Oxford, and make arrangements with the Secretary to procure some gentleman to judge who does know an Indian Game fowl when he sees one. After we had inspected these we set out for a "good constitutional," and paid many birds afternoon calls in their farmyard runs. Some would not respond, for they had already gone early to bed on that chilly November afternoon; but we were able to see them, and so in the November journey we drove back again to Cirencester to have the pleasure of renewing our acquaintance with many of those newly made feathered friends a few days afterwards in the Sydenham Palace, and glad we were not a little to find on that occasion that in that brilliant collection of old England's oldest breed of fowls one of the silver trophies had most deservedly been bestowed on a specimen from Bibury, Fairford.—W.

ABERDEEN SHOW OF POULTRY, &c.

THIS, the eleventh Exhibition of the Northern Poultry and Pigeon Club, was held in the Music Hall on the 11th, 12th, and 13th inst., when the following prizes were awarded:—

- POULTRY—Game—Black Red—Cock—1, W. Deen. 2, A. Brown. 3, — Cock—Hen—1, Booth & Toth. 2, J. Mackintosh. 3, J. Ballie. Brown Red—Cock—Cup, G. Peter. Cock—Hen—1, W. Deen. 2, A. Brown. 3, J. Ballie. Hen—1, A. Stephen. 2, J. Barrie. 3, T. W. Mitchell. Any other variety—Cock, 1, J. Ballie. 2, T. W. Mitchell. 3, A. Stephen. Hen—1, A. Mitchell. 2, T. W. Mitchell. 3, T. W. Mitchell. 4, T. W. Mitchell. 5, T. W. Mitchell. 6, T. W. Mitchell. 7, T. W. Mitchell. 8, T. W. Mitchell. 9, T. W. Mitchell. 10, T. W. Mitchell. 11, T. W. Mitchell. 12, T. W. Mitchell. 13, T. W. Mitchell. 14, T. W. - 3, W. Matthew. Cockerel—1, W. Snowie. 2, A. Allan. 3, Mrs. Grant. Pullet—1, 2, and 3, Mrs. Grant. Silver-Grey or White—Cock—1, Mrs. G. Armistead. 2, J. Masson.

Hendon hen was prettily marked and large. The cup went to Crèves, and a good pen they were, extremely deep in colour and massive in frame; a good pen of La Flèche taking second honours, and Crèves again third. *Leghorns* had a class in which both c'sours completed, and Whites were first and third. In *Minoræ* good Blacks were first and Whites second, but they carried too much of comb for our taste, as did all the prize pens; third, again, was taken by Blacks. The Variety class was excellent; we noticed some splendid Sultans and good Silkies. The *Bantams* alone made a show of themselves, and the cup Black Reds were good in colour and very stylish; and in Brown Reds the best pen secured the cup. The cock very pretty in head. In Laced the first was won by a pair of Silvers, even in markings and fairly small. In the variety Bantam class Blacks were first, and good Booted second. Thirteen pens in this class were noticed by the Judge.

The *Waterfowl* were good. The first Aylesburs were big and clear in bills, while in Rouens the cup pen was of fine colour and very large. In East Indians the cup remained in the county. We were glad to see a new name in the prize list, though that of an old fancier of the breed; winning seems all the season to have been monopolised by two or three yards. The second were very letrous and neat in shape; third (Mr. Sainsbury's) were in beautiful bloom, and we are glad to see that he has changed his mind in not retiring. The Variety class of the beautiful, quite a sight of itself, and fifteen pens of the seventeen entered had cards. The cup pen was Carolinas in exquisite bloom.

Among the *Pigeons* the Pouters were of high merit, Mrs. Ladd's grand White scoring another cup in hons; the second was Mr. Holme's celebrated Blue. *Tarbits* were excellent; Mr. Burnell and Mr. Cresswell having a close contest for premier honours in the Any other colour class. *Fantails* were splendid, Mr. Serjeantson's Whites being marvellous in tails and carriage. Nuns had seven pens, and the Judge awarded the prizes, all three of them, so we may believe that for once they had not been so over-dressed as not to pass muster. We were pleased to see so many Archangels and so much quality among them. The winners seem to have been well selected, and an extra second was given. The *Dragons* were very strongly represented, and Mrs. Bishop and Osmond sending large teams, and not having Mr. Wood to oppose them, had to have among the prizes, though Mr. T. C. Burnell came in here and there with some good birds. Mr. Bishop won the Dragon point cup with, we believe, six points. In the Variety class Austrian Pouters won first and Frillbacks second. In the collections Mr. Baker came in a good first and took the cup, as too he did the third prize as well.

We hear the prize money has already been paid, and that the birds were very speedily dispatched at the close of the Show.

ACCRINGTON PIGEON SHOW.

The first Show of the Accrington District Columbaria Society was held on the 19th and 20th inst. This Show was promoted principally by Mr. Sutherland, the Secretary, assisted, however, by a good Committee, and for a first attempt was most excellently managed. There were upwards of three hundred entries, which quite filled the room.

Pouters were good but few, and Carriers, though in the hands of but three exhibitors, were very good. In cocks Blacks won, and in hens Duns. The first in the latter class a ospital bird, on which we have often commented before as excellent in eye-water. In Barbs the winners were Blacks, the cocks all noticed. Mr. Yardley's grand hen was first in that class. There was a good class of young birds, though some exhibitors, the loers especially, contended that the winners were rather old-fashioned birds. In the collection of young birds the winners being Reds. First an exquisite little Red hen, the second and third cocks. In Owl first was the Silver so often referred to of late, the second an excellent Blue. In hens the winners were all Silvers, and many more deserved a place. Nuns and Magpies both very good; the winners in Magpies were all Reds. Almond Tumblers added another clean sweep to the Yardley loft, and in two cocks and one hen there was very little to choose. *Fantails* were superior. In *Dragoons*, Blue or Silver, Walton-on-the-Hill seems to be gaining ground, for here was scored another victory to that loft with a Silver first and a Blue second. The third, a little too large, was otherwise a fine one. In the next class a Red was first, and Yellows second and third; and in the young class first was a Yellow and second a Silver. *Dragoons*, any other colour, were—first Blue Queen, as also the second, and third a Grizzle. Antwerp were good in all classes, and in Shortfaceds we see a tendency to the correct type rather than to the mediums so often shown as Shortfaceds of late; and in Long-faces the style and colour is far in advance of what has been done for the last few years. In the Variety class first was a White Owl, second a Black Swallow, and third a White Owl; and in the Selling class first was a pair of Yellow *Dragoons*, second Black Barbs, and third Blue *Dragoons*. There was an excellent class of flying Pigeons, most of which were said to have done extraordinary distances; there were, however, some very likely birds.

PIGEONS.—*Pouters*.—Cock.—1 and 2 J. Kendall, *Hen*.—1 and 3 J. Kendall, *Carriers*.—Cock.—1, 2, and vhs. J. Kendall, 3 E. Dawson, *Hens*.—1 and 2 J. Kendall, 3 E. Dawson, 4 J. Kendall, 5 E. JUDGES,—Messrs E. Hutton and W. Sefton.

THE BELGIAN HARE RABBIT.

The Belgian Hare Rabbit claims much attention owing to its value as food, as it averages a larger weight than most other breeds; its average weight is from 8 to 10 lbs. Its original home is on the Continent and it is not, as the name might seem to imply, a cross between the Hare and the Rabbit. Such crosses have been occasionally attempted, but have never been successful, the progeny, whenever the cross has been effected, being an infertile mule. The name Hare seems rather to be present as a sign that resemblance to that animal must be cultivated in breeding. The breed is now kept to a considerable extent, although till lately it has not been popular.

The Belgian Hare should possess a large bony frame, well proportioned, but slightly inclined to be lengthy; the head of fair size, and the face long and nose sharp. The colour should resemble that of the Hare—i.e., it should be of a brown grey colour, or more correctly speaking a red grey. The animal is always of one colour, though of course the shade will vary. The back and rump will be darker than the sides, and this may be considered an advantage rather than otherwise. The under parts will be much lighter, in some cases approaching pure white. However this may be, it is imperative that there should be no white visible when the animal is either standing or reclining. If there be any it will most decidedly destroy the animal's chance of success at any show. The legs, in accordance with the shape of the body, should be firm and well set. In colour the outsides should be grey and also the insides up to the first joint; above this the colour is generally lighter, and sometimes almost white. Neck long and of a uniform grey colour. The head and face is also of this colour, the throat being generally a trifle lighter than the face. Ears long, but quite upright; they are of a dark grey shade, and there is a black streak going up the side. This streak is very important, as both showing off the animal and indicating breed.

The specimens of this breed should possess a fair-sized dewlap. There has been much controversy on this head, but the majority of fanciers seem to be breeding in this direction. A glance at the merits and demerits of it may not be amiss. In the first place, it is urged against it that the Hare never has a dewlap, and that the merits of a Belgian consist in the resemblance it bears to this animal. This is true no doubt, but the advocates of the dewlap reply, Neither does a Hare arrive at the weight of 10 and 12 lbs., and if the dewlap is to be done away, reduce the size upon the same principle. No one will be disposed to do this latter, and hence the question of dewlap is undecided. Then, again, is not dewlap the result to some measure at least of good food and attention? Take two young Lops from the same litter and let them be reared by two different persons, one by an experienced Lop breeder, the other by an embryo connoisseur, and when twelve months old compare them. Number 1 will be fat and well dewlapped, while number 2 will be thin and without any signs of that appendage. Are we then to condemn the natural results of good care and attention? Both the dewlap and increase in size are simply and solely the result of domestication, and they must stand or fall together. If the dewlap is wrong, size is wrong too, and the objectors to the appendage will hardly care to have the latter done away with upon the same principle as the former.

The general appearance of the Belgian Hare is thus very easily described—a large roomy frame, large head and legs, long but upright ears, a clear fawn eye. The colour we have said is grey. The only parts that can legitimately be of any other colour are the under portions of the body extending sometimes slightly down the inner sides of the legs, the lower portion of the tail and some parts of the throat, although this latter must not be of sufficient quantity to be visible except on close examination; it is, in fact, best away altogether. The following is an easy scale of points; it takes in most of the properties, but if any reader can suggest an improvement, if he will kindly write a short note on the subject he will be doing a good deed, as the properties are by no means thoroughly acknowledged among fanciers nor are the relative values of them plainly fixed:—

Colour	15
General shape	10
Shape of head	5
Ears	7
Eyes	5
Underparts	3
Condition	5 = 50

The Belgian Hare is not a Rabbit that would be selected as a

pet so much as several of the other varieties, because in the first place it is not particularly docile, and in the second place because although it is handsome it is not by any means pretty. The breed cannot be said to be very prolific, the litters not being large or frequent. The young are pretty hardy at birth and grow very rapidly, and after a few days become strong and hardy. They are not so much subject to the usual intantile complaints that work such slaughter among young Rabbits in general. The litters will average from three to six, and the doe will breed three or four times a year. They can then only be spoken of as not prolific in a comparative sense, as twenty young ones may be annually reared from each pair; and although double that number can be produced from some does, I think but few will raise a greater number. For a few weeks the young present the appearance of ordinary hutch Rabbits, and it is not till they are a couple of months old that the ear tipping, &c. are apparent, and these are the great indicators of the breed.—G.T.A.

HIVES AND LOCALITIES.

Your correspondent Mr. Lowe is quite right in saying that the question of hives crops up to the surface now and then, and as it is one of some importance, often viewed from different standpoints, the discussion of it generally commands the attention of a large circle of readers. Amongst practical bee-keepers the subject is always interesting if handled in good temper. It is to be regretted that parties differing in opinion have not always abstained in their discussions from the use of harsh words. If it is beyond the power of apiarians to keep fool brood out of their hives, surely it is not beyond their power to keep it out of their communications.

It is well known that I use hives that are capacious and comfortable, simple in construction, low in price, and passable in appearance. Hives possessing these points compass all I want. In the breeding seasons bees should have room for setting and hatching the eggs, laid by their queens, and space enough for honey as well. As for comfort and convenience I have never seen any better than good straw hives. I have never found hives made of other materials that allowed the moisture of bees to escape readily and without injury to the combs. At certain seasons materials other than straw condense the moisture on their inner surfaces. Many plans and experiments have been tried to prevent the condensation of moisture on the inner sides of wooden hives. "The Quilt," which is an American idea, has been tried in this country without success so far as I know. Mr. Yates of Manchester felt sure that he would succeed by covering his wooden hives with boiler felt, which is warm stuff about 2 inches thick. This did not answer. Ventilating holes in the sides and crowns of hives have been tried with greater but not complete success. I believe that the question of ventilation will receive greater attention by-and-by than it has done in the past. During the summer, when the heat of hives is very great, their internal moisture is driven out through their doors by the heat and natural ventilation of the bees; but in spring and autumn the sides of wooden hives are often streaming with condensed moisture. I hope that a cheap and satisfactory mode of ventilating wooden hives may soon be discovered and made widely known.

A few weeks ago the readers of this Journal were favoured with the records of capital results in bee-keeping from hives of various kinds. Mr. Briscoe of Albrighton obtained 144 lbs. of super honey from a Stewarton live. The story of his success appeared in the Journal of October 12th. The week following Mr. P. H. Phillips of Hitchin told us through the same channel how he obtained 131½ lbs. of honey in supers from a straw hive; both gentlemen are advanced and clever bee-keepers. It will be observed that the straw hive was 12½ lbs. short in super honey of the Stewarton live. Now let me here say, that if the Stewarton had been 12 or 20 lbs. short of the straw hive I would not have ventured to say that the greater result was due to the hive, for one hive may have been stronger at the commencement of the season, or it may have fed on better pasture than the other. A small field of white clover near one of the hives may have given it the advantage and victory. Rain often hinders bees in one county, while sunshine helps them in another. The hives of both gentlemen swarmed in the middle of summer or honey season, and as both gentlemen are experts they cut out the royal cells containing young queens (from the mother hives) and returned the swarms to them. This operation of cutting queen cells out of hives after swarming is easily done.

I will now attend to the following question:—If you have been comparing hives that belonged to gentlemen living in different parts of the country; will you please to notice the difference of the results between the Stewarton and the straw hives of the 'RENFREWSHIRE BEE-KEEPER.' In 1875 the Stewarton hive of this gentleman yielded 68 lbs. of super honey. The straw hive standing beside it yielded only 2½ lbs. The straw hive after yielding the 2½ lbs. of super honey was, we are told, in a starving condition. When I read the letter of your Renfrewshire correspondent it struck me that the one hive was healthy and

the other was not. If both hives were healthy the question of "W. J. C.," page 563 (a correspondent unknown to me), has hit the mark exactly. He asks what the bees in the straw hive were doing while the Stewarton gathered 68 lbs. May I not venture to assert that never before has it been known that the bees of healthy hives filled a super of 20 lbs. while the cupboards below were quite empty? Charity begins at home, even in a bee hive. We know that in Lanarkshire and other parts of Scotland swarms in straw hives and the stocks that yielded them in 1875 rose to 70 lbs. or thereabouts, whereas the straw hive of your Renfrewshire correspondent, which never swarmed at all, was at starvation point after its super of 20 lbs. was removed. If our friend is correct in tracing this failure to the materials or construction of the hives, and if his logic is trustworthy, we may safely conclude that Mr. Phillips, who obtained 131 lbs. of super honey from a straw hive in 1876, would have obtained nearly 400 lbs. of super honey if his bees had been in a Stewarton hive instead; and what would Mr. George Fox say if he were told that he would have obtained three supers in 1876, each 86 lbs. in weight, if his bees had been working in a Stewarton hive instead of a straw one?

While writing these last few lines the post has brought me a letter from a gentleman in Cambridge asking where straw hives can be obtained. Having made a few complimentary remarks about me and my book, he puts the following question—"Do you, after seeing the reports of the large takes of honey from the Stewarton hive, still adhere to your first preference to straw? All other modern books on bees which I have read speak little or nothing of the hives, and if his logic is trustworthy, we may safely conclude that Mr. Phillips, who obtained 131 lbs. of super honey from a straw hive in 1876, would have obtained nearly 400 lbs. of super honey if his bees had been in a Stewarton hive instead; and what would Mr. George Fox say if he were told that he would have obtained three supers in 1876, each 86 lbs. in weight, if his bees had been working in a Stewarton hive instead of a straw one?"

polling of his hands coming into possession, was the Stewarton with all its parts moveable, and he sticks to it.

ENING AND ITS CONSEQUENCES (E. G., Co. Down).—By king you presented your bees from swarming in the summer of both 1876 and 1876. Your hive is now a large heavy one, but if you had let the bees swarm last year you would have had two or three stocks instead of one. Abstain from king this year, and let the bees swarm twice if they will. About three weeks after the first swarm are obtained drive all the bees out of the old hive into an empty one, and take the honey. The combs in it are old and black, and the queen too.

ERBATICM.—"A Bee-keeper's Retrospect," page 53, read *schools* instead of *schools*.

FINE BOARDS FOR HIVES (J. M.).—Thick-wooded hives are an exploded idea. Bees and their combs are not dried and best in hives of pine wood five-eighths of an inch or so thick, always provided they have thorough external protection from the weather by means of an outer case of wood, good straw hackle, or other efficient protector to cover all the hive saving the entrance, and run off all moisture.—A RENFREWSHIRE BEE-KEEPER.

FLOWERS FOR BEES (F. F.).—Farrar being a honey plant in the second or third class was not named in the list of first or second class of honey-producing plants which you refer to. You think some of your snipers were filled with honey gathered from the furze bushes growing on a heath between one and two miles distant from your garden. Very likely some of the honey was brought from the heath or grown growing on the heath, but we are of opinion that most of the honey of your snipers was gathered from other kinds of plants. Bees that work on broom and furze are well waded over with pollen, and appear as yellow as soldiers and dusty as millers.

REMARKS.

- 17th.—Dark showery day, but a starlight night.
- 18th.—Another day and night bright.
- 19th.—Wet calm; dry and windy after and in the night.
- 20th.—A dry and very pleasant day, colder towards night; barometer unusually high; a fine sunset, and a bright starlit night.
- 21st.—A very dense fog, particularly so from 10.30 to noon, then cleared off, but left a very bright pleasant afternoon, evening, and night; haze halo.
- 22nd.—Slight white frost in morning, followed by a bright sunny day.
- 23rd.—White frost and rather foggy early, but again followed by a very bright pleasant sunny day.

First half of week damp, and uncomfortable; the last three days very pleasant. Temperature about 3° above last week.—G. J. SYMONS.

COVENT GARDEN MARKET.—JANUARY 24.

The supply of early forced vegetables, such as Asparagus, Spinalke, New Potatoes, and Rhubarb, is now very general, and prices low; but Cucumbers, owing to so much dull weather, are short, and in good demand. Late Apples are in fair request at firm rates; Kent Cobs quiet.

OUR LETTER BOX.

CHUELY (Hub-a-lub, &c.).—We must decline entering upon the subject. It would include topics from birds in cages to horses in harness.

BEARNA HEN (J. A. Bames).—The symptoms (drooping of the head and walking backward) demonstrate that she has a pressure on the brain. She is probably too fat. Give her a dessert-spoonful of castor oil, and keep her on low soft diet—two-third barley meal and two-thirds pollard mixed together with water.

COCKSHEL (Crib).—He has a catarrh. Let him eat only in the middle of the day. Give him a dessert-spoonful of castor oil, and feed him only on soft food—barley meal.

SILKIES (E. B. Norrick).—The most likely way to find purchasers will be by advertising the birds. A wry tait in the Hamburg cockerel is not likely to become straight.

SCHEDULE OF THE AQUARIUM UNITED KINGDOM POULTRY AND PIGEON EXHIBITION.—We are informed that Cape No. 6, and 7, value five guineas each, are for Dark and Light Brahmas respectively.

HIVE (Ed).—After prolonged trials of many hives and systems, storing and wintering, the Renfrewshire Bee-keeper found the one that yielded the largest harvest of pure honeycomb and consequent profit, with least expenditure of time-watching, the least disturbance of the stock, and

From observations taken near London during forty-three years, the average day temperature of the week is 46.1°; and its night temperature 32.8°.

FORCING POTATOES, CARROTS, AND DWARF KIDNEY BEANS.

POTATOES.—These are often planted in large forcing establishments earlier than the present time; but I have always found the best results follow from tubers which were planted after the new year has commenced, for then they grow freely from the first, and there is not so much danger of their being checked when advanced in growth as those which are planted early in a place where there is no artificial heat.

I do not start my tubers into growth, as some of your correspondents have recommended lately. Previous to planting the sets are spread out in a shelved shed, where there is plenty of light. The sprouts are only about 1 inch long when planted, and instead of being weak and tender (like those started in heat before planting) they are strong and hardy, and always grow away without receiving the slightest check; and it is difficult to avoid checks with tender drawn-up growths. Anyone with a three-light frame and a cartload or two of leaves and stable dung may have young Potatoes in May. We have finished putting in ours a day or two ago, but Potatoes put in now, or during the next week, would come in about as early. The leaves and manure should be mixed up in a heap in about equal parts, or there may be more leaves than dung. Let the heap lie until fermentation begins, which will be in three or four days. Turn it then, and in two days afterwards it may be put in the frame. When placed in the frame the heating material should be at least 2 feet deep and firmly trodden down with the feet. Above this place 12 inches of common garden soil mixed with a little of the decayed manure which was used for planting or forcing the year previous. When all is filled in the surface of the soil should be from 15 to 18 inches from the glass and quite level.

Place the tubers in the soil 6 inches from the surface. When this has been done put on the sashes, but open them a little on all fine days, closing them again at night, and unless in frosty weather never cover the glass. As soon as the leaves are seen above the soil give a thorough watering. When the growths are a few inches long the sashes may be removed altogether on fine days when the wind is not "cutting." The frame should always face the south so as to catch all the sun heat. Kidneys that do not produce big haulms may be planted 15 inches apart between the rows and about 4 inches between the tubers. Round sorts must have a little more room. My favourite varieties for forcing or planting at this time are Veitch's Improved Early Ashleaf, Myatt's Prolific Ashleaf, and Early Frame. I never earth-up my frame Potatoes. Giving air and water when required is the whole of the attention they receive from the time they are planted until they are lifted for use.

CARROTS.—These are sown about the same time as the Potatoes are planted, and they are ready for use equally early. The hot manure for both is mixed in the one

heap, but 1 foot deep of it is sufficient to bring up and on the Carrots. It is put in the frame as for the Potatoes, but not so far from the glass. The soil used is a light leaf soil and sandy mixture, and this only to the depth of 6 inches. When ready for sowing the surface of the soil is 1 inch from the glass. I use the Early Horn. It does not grow large, but the roots are always clean, tender, and of excellent flavour. The seed is sown broadcast, and covered over with half an inch of the mixture similar to that underneath it. If the seed is good sow thinly. Do not water until the young plants are visible, and very little air need be given until then. Thin out the plants before they are crowded, leaving them 2 inches apart; do not let them suffer for want of water afterwards, and admit abundance of air on all favourable opportunities. In drawing them for use, pull out the largest and let the smaller have more room to develop.

DWARF KIDNEY BEANS.—These require more accommodation than either of the foregoing, but at the same time they may be grown from now onwards with less trouble and more success than some may suppose. We have gathered pods as early as this, but they were neither so fine nor so abundant as from those raised by sowings in January, February, and March. I have tried a good many sorts of these Beans for forcing, and I have now limited myself to Osborn's Forcing. This is a first-rate sort in every way. Three dozen pots supply a good quantity of Beans. The pots used are 8 inches in diameter. A few crocks are placed at the bottom of each, and the pots are half-filled with a compost consisting of light loam and leaf soil; this is pressed down firmly, and eight or ten seeds are laid over the surface and covered with 1 inch of soil. When the soil is moist no water is given until the rough leaves appear. The plants grow freely in a temperature of 60°. Much water must not be given at first or it will rot the young plants. While growing let them have all the light possible. The above-named temperature suits them throughout.

As soon as the leaves are fairly above the pots the remainder of the soil that is required to fill the pots must be added. Press this very firmly, and let it be a little lighter than that used at sowing time. When the plants come into bloom they are benefited by a little air every day, but this must depend on the outside weather. A few birch twigs put in as the plants ascend saves them from falling over, as they are liable to do as the fruit swells. Red spider is sometimes troublesome, but syringing never fails to keep it in check. Pods may be gathered five weeks after sowing the seed.—A KITCHEN GARDENER.

LOTHIAN STOCKS.

No Stocks are more valuable for winter, spring, and summer decoration than are these. Sowing the seed in July and August has been frequently recommended, but I find, after many trials, that those periods are too late for producing the best display of which these sweet and massive flowers are capable.

It may be well to explain what I mean by the "best

display"—I mean large plants of double white, purple, and scarlet Stocks in the depth of winter. It is easy to obtain Stocks in spring and summer, and even at those seasons they are beautiful when the plants are well grown; but they are far more attractive from November until April, and withal they are easily produced at that period. When the sowing of Lothian Stocks is deferred until July or August the plants do not flower until late in the following spring, continuing through the summer precisely when other Stocks are plentiful. The true Lothian Stock, it should be remembered, requires a longer period of growth before flowering than does the ordinary type of the Intermediate Stock; the Lothian also lasts considerably longer after it commences flowering than the London Intermediate—indeed longer than does any other Stock in cultivation.

Seed sown in February or early in March produces plants which, if well managed, commence flowering about July and continue until destroyed by frost. Such plants make most effective beds in the flower garden—beds as decided in their beauty and lasting as long as any other "bedding plants." As thus managed Lothian Stocks are very valuable. July and August sowings, as has been mentioned, produce plants which flower in spring, lasting also a considerable time; but the time of sowing for producing the "best display" I have found to be April, say, for the purpose of fixing it on the memory, on All Fool's-day. By sowing at that time I have had plants in 8-inch pots—plants 18 inches high and about as much in diameter, perfect masses of double white and scarlet flowers (the purple is not so effective during winter) at Christmas and onwards until April. It is not necessary to dwell on the value of such plants for affording an abundant supply of cut flowers of the first order of merit, neither is a laboured eulogium necessary as to the commanding effect of the plants in the conservatory. At their period of flowering few plants can equal them, none surpass them.

My plan of raising the plants is to put up a bed of leaves and litter about 2 feet high, nail four boards together to form a rude frame, and cover the bed with frame lights. Four or 5 inches of soil is placed on the bed, and in this the seed is sown thinly, very thinly, in drills. The plants are thinned to an inch or more apart as soon as they can be handled, and the glass is removed entirely during favourable weather. About the middle or towards the end of May the plants are very sturdy, and are potted into small pots just vacated by bedding plants. In these small pots the plants remain until they show flowers, when the spike of each double flower is cut off. Side shoots speedily grow, and as soon as these are seen the plants are potted firmly in rich soil in their blooming pots. These are placed on a hard bottom so that the roots cannot penetrate into the ground to any great extent, and a little litter is placed between the pots to aid in keeping the roots cool and moist. The plants are subsequently treated as to watering the same as are *Chrysanthemums*, giving them liquid manure occasionally. They commence flowering in October, and an inch of the surface soil is then removed from the pots and replaced with a rich top-dressing after the manner of surface-dressing fruit trees in pots. The plants are then placed under glass and in a minimum temperature of 45° to 40°. They flower splendidly all the winter.

That is the best way that I know of producing the "best display" of Lothian Stocks. The plan is applicable to most gardens, and when plants are well grown they are worthy of a place in the most choice collection of conservatory plants during the winter months.—A NORTHERN GARDENER.

PRUNING VINES.

SOME Vine-growers in giving directions for pruning lay down one rule as suitable to all the varieties of Grapes; but there are exceptions to all rules, and Grapes, such as Muscats and a few others, require different treatment from Black Hamburgs in the way of pruning. This productive and useful Grape does very well with close pruning, but I have always found Muscats to succeed best by leaving two or three eyes to the spur, of course rubbing off all but one when it could be discerned which was best. I have even in some cases left a side shoot from 1 to 2 feet in length, and when I see a bud on any favourable portion of the rod between the spurs I encourage its growth, supposing I have space for two or three leaves. By doing this the spurs never become unsightly, and besides it promotes the health and vigour of the Vine.

I may add for the benefit of some of the amateur readers of the Journal that I have always found Tynningham Muscat

easier to manage than Black and White Frontignan and a few other inferior sorts, and it is superior to both Grapes named in appearance and flavour. I do not say Muscats are so easily managed as Black Hamburgs and a few other Grapes, but certainly they are not so difficult as many are led to believe. Anyone in possession of a vineyard may grow Tynningham Muscat, which is one of the finest flavoured white Grapes in cultivation. I have grown it for nearly fourteen years, and during all that time its productions have been most satisfactory.

In the above remarks I allude to mixed houses: in large establishments where a whole house can be devoted to the growing of Muscats no doubt they can be brought to a higher state of perfection, but few have such accommodation; therefore I hope what I have stated may be of service to some amateurs. The pruning of Vines should now be completed as speedily as possible.—J. DICKSON.

EARLY BRUSSELS SPROUTS & CAULIFLOWERS.

A LETTER from Mr. R. Gilbert, Burghley Gardens, has been sent me by the Editors of the *Journal of Horticulture*, from which I make the following extract—"A MARKET GARDENER," on page 26, says he sows Brussels Sprouts in September. I have done the same for three years in succession, but my plants have run to seed. Sowing in February in beds slightly heated is a plan I follow yearly with the best results."

My reply to that is, that only during one year out of more than a dozen have my autumn-sown Brussels Sprouts run to seed, and that year I sowed earlier than usual, and the winter, like the present one, was unusually mild. The plants were very large—too large—when planted in April, and, like my autumn-sown Cauliflowers, the crop was a comparative failure. I fear that I am much in the same position this year, but inadvertently omitted saying so. It was, however, because of the prospective failure of my autumn-sown plants of both Brussels Sprouts and Cauliflowers that I laid stress on the importance of sowing seed under glass in January.

My plants are much too forward this year, as are those of many others. It has been impossible to prevent the plants from growing too large during the winter, and I much fear it will be equally impossible to prevent the Cauliflowers from "buttoning" and the Brussels Sprouts from "running" during the ensuing spring and summer. I would send Mr. Gilbert a few plants, but as I anticipate they will most of them "run" it would be useless my doing so. That, as before stated, is why I urged as important the raising of plants under glass by sowing a little seed at the present time of both Brussels Sprouts and Cauliflowers.

These are important vegetables, and the value of the crops is enhanced by having them ready for use early in the season. It is very common to sow Cauliflowers in gentle heat at the present period of the year, but not nearly so common to raise Brussels Sprouts at the same time and in the same manner, yet I have always found the latter crop as valuable as the former. By sowing seed of Brussels Sprouts in September I have been able to produce an ample supply of this esteemed vegetable early in August. At that period of the year Peas have sometimes been scarce owing to drought, and also by the same cause have Cauliflowers: the "Sprouts" have consequently been specially acceptable.

I am glad to have received Mr. Gilbert's suggestive letter in reference to the running of autumn-sown Brussels Sprouts. The matter is one of considerable moment and worthy of being more particularly alluded to. The primary cause of the plants running is their being too large at the time of planting them. The larger the plant the greater usually is the check it receives by its removal. Smaller plants, however, will run if not carefully managed. If the plants are denuded of a large portion of their fibres in the course of removal, and sunny days and frosty nights follow their planting, the plants wither considerably and their stems become hard—"woody." Such plants are very liable to run whether they have been sown in the autumn or have been raised under glass early in the spring. The great point to secure is to keep the plants steadily growing and their stems succulent. In a winter like the present it has been impossible to keep the plants "steadily" growing, for they have grown rapidly and are now dangerously forward.

I sow my Brussels Sprouts late in September. The plants do not grow so quickly as do Cauliflowers, and at this period of the year plants of the former are generally quite small. During February or early in March, according to the weather, a few for the first crop are selected and are pricked into square

inverted turves—turves from the roadside cut into small squares of 3 or 4 inches in diameter, a plant being placed in the centre of each square of turf. These are placed nearly close together, and leaf soil is sprinkled in the interstices between the turves. The plants are then protected with glass for a short time, and afterwards with mats when the nights are cold. The plants are in splendid condition for finally planting at the end of April, and receive no check by removal or a term of bright sunny weather, and in ordinary seasons they do not "run." I adopt that plan also with plants raised in heat in spring and with *Calliflower* plants similarly raised, and I can recommend the practice as being worthy of general adoption. I formerly (as do many gardeners) potted a portion of my early *Calliflowers* and *Brussels Sprouts*, but since I have proved the value of the turves pots are used for other purposes. The plants thrive better in turves than in pots, and become more quickly established when planted out. The little trouble necessitated in carrying out the plan is trifling in comparison with the great advantages eventually resulting.

—A MARET GARDENER.

CLIMBING ROSES.

THE interesting article on page 41 of the *Rose Journal* on climbing Roses will be read by many with delight; but I venture to think the great majority of your subscribers will regard the author with compassion as one who, while he may drink *Cabateau Lafitte*, is content to quaff huge tankards of sour cider.

Fancy *Amadis*, *Thoresbyans*, *Alice Gray*, *Félicité Perpetua*, and *Dandee Rambler* occupying space which may and should be covered by *Cloth of Gold*, *Maréchal Niel*, *Madame Trifle*, *La Belle Lyonnaise*, *Solfaterre*, *Climbing Devoniensis*, and *Cheshunt Hybrid*. What is a bushel of *Crab Apples* compared with a handful of *Ribston Pippins*? What difference is there, too, between the free-flowering propensities of any of the above-named varieties when once established and even *Alice Gray*? Why, you might as well plant wild *Briars* against your church as *Alice Gray* and *Bennett's Seedling*. I am not speaking without good reason, for I have grown all the sorts which the "PARSON'S GARDENER" names. Though a "WILD SAVAGE," I am a shepherd of the sheep, and a parson's gardener also, inasmuch as I am my own head gardener and a parson to boot. When I first came here I planted all the climbing Roses named by "A PARSON'S GARDENER" against my church in order to have *Roses* as quickly as possible; but when these plants bloomed—and they did bloom in a manner perfectly wonderful—the blooms individually were not worth looking at. The effect from a short distance was grand and worthy of all the encomiums of your correspondent, but when you have said that you have said all. The blooming season, too, is so short that for about ten months of the year your walls are destitute of a single flower. I soon pulled up my plants and gave them away; and now let me tell "A PARSON'S GARDENER" those I have replaced the summer *Roses* with.

On the east wall is *Cloth of Gold* and *Clematises Jackmani* and *Prince of Wales*. On the south wall of the chancel *Maréchal Niel*, *Cheshunt Hybrid*, and *Cloth of Gold*, together with *Passiflora carnea*, *Clematises Rubella*, *Miss Bateman*, *Lady Caroline Nevill*, and *Lady Lonsdaleborough*. On the south side of the nave, *Solfaterre (Noisette)*, *Climbing Devoniensis*, *Madame Trifle*, *La Belle Lyonnaise*; *Clematises lanuginosa nivea*, *Standishii*, and *Albert Victor*. On the north side of the church I friskily own I do not attempt to grow anything, and perhaps I might place *Amadis*, *Alice Gray*, &c.; but I do not think even these hardy summer *Roses* would do well there, as huge *Conifers* so shut out the light that it would be hopeless to attempt it.

I wish "A PARSON'S GARDENER" would pay me a visit in June and I would return the compliment, and then we could compare notes and see which system answered best.—WILD SAVAGE.

INSECTICIDES.

THE sulpho-carbonate of potash has for some years been considered in France as the best insecticide, and is, I presume, easily obtainable in Paris, and at a reasonable rate. But as I never see in England any advertisement on the subject, I imagine it is either unknown in the trade, or else sold under a fanciful name as one of the numerous high-priced nostrums. I should like to know whether it possesses any advantage over the

sulphuret of lime so long known, and the recipe for which has so often been given in your columns.—G. S.

THE LILY.

I QUITE agree with "G. S." in your number of the 7th September last that the continued importation of *Lilium auratum* is surprising, for the sale of several thousands of bulbs in one day in an auction room has for many years past been an ordinary occurrence. But when he asks, Where are they now? I am not surprised when he himself replies, Why, dead.

An immense number of the imported *Lilies*, as "G. S.'s" experience shows, are worthless to the amateur. In fact, they can be of no value to anyone but the nurseryman, who has room to spare and can afford to plant them out for a season or two; weeding out from time to time the dead and the dying, and replanting the better bulbs. By doing this, and purchasing them in the first instance "for a song" as the auctioneer says, the nurseryman is able to supply good bulbs at a moderate price. I think this is borne out by Mr. T. Clements, who, in his communication to you on the 21st of September, stated that the bulbs procured from a nurseryman flowered the first year after planting, and every year increased in strength and number of flowers. I will venture to say that they were not newly imported.

I now wish to correct what I consider to be a very grave mistake, and one that goes to the root of all improvement in *Lily* culture. We often hear remarks somewhat like the following: "Last year one of my bulbs sent up a flower-stem 5 feet high, and this year the same bulb threw up one 7 feet high crowned with thirty flowers." Remarks like these are calculated to mislead, for the same bulb did nothing of the kind. It was the successor of the former bulb that produced such a display, for a *Lily* bulb can only flower during one season. It is a mistake, then, to offer bulbs which are stated to be one, two, and three years old. The size of the bulbs are not increased by age merely, but by culture. This is exemplified to a great extent by what Mr. Clements has stated. He planted bulbs of *L. auratum* among his *Rhododendrons*, the soil consisting of sandy loam and peat together with a quantity of white sand; and "the first year after planting they made a good display, and every year increased in strength and number of flowers." This is the secret—congenial soil.

The question arises, How long should the bulbs be allowed to remain in the ground without being taken up and replanted? *Lilies* are such gross feeders that they soon impoverish the soil; and those which produce many offsets impoverish the parent bulbs. If the desire is to have large and handsome flowers, the bulbs should be taken up periodically when the leaves decay, and all the small offsets detached from the principal bulbs, reserving only the largest roots to plant again in their proper places. Some *Lilies* are the better of being taken up and replanted every year; and I know of none that can benefit by being kept in the ground more than two or three years. I know that this is not the opinion of many; but those who will take the trouble to study the real nature of the bulb will appreciate what I say. The bulbs may be taken up at the proper season and replanted with fresh soil without the slightest check; but the valuable kinds should be handled with care, and none should be kept out of the ground a moment longer than is absolutely necessary; for everything that tends to dry up the scales, as in the case of dried-up imported bulbs, tends to diminish the nourishment that Nature has provided for succeeding bulbs. It is well to remember that *Lilies* of the European class thrive on more homely fare than those of warmer climates. Some thrive on very dry food, while others require much moisture.—DUNEDIN.

PINE APPLE STEMS SHRIVELLING.

THE remarks recently made in these pages on *Pine Apples* I have read with much interest. Neither of your correspondents has made any allusion to shrivelled stems. Most cultivators have seen more or less of them, especially in the winter fruiter; therefore, with a view of eliciting the opinion of the readers of the *Journal*, I have called attention to the matter. We have cut during the last three months from twenty to thirty fruits of different sorts—*Smooth Cayenne*, *Charlotte Rothschild*, *Prince Albert*, and a few *Queens*, which threw up fruit late in the autumn. What seems most perplexing is that some of each sort should shrivel at the base of the fruit just before commencing to colour, while others growing in the same

house side by side, treated the same as to soil, water, temperature, &c., remained plump and firm till fully ripe. In turning the old stools out of the pots they are about equal as to roots. They have been since showing their fruit in a light house at a distance of about 2 feet from the glass, plunged in a tan bed, bottom heat 85°, top heat 65° to 70°, the path sprinkled once or twice a-day according to the state of the weather. Should any of your correspondents have experienced the same difficulty, and will give through the pages of the Journal the benefit of their experience, the undersigned will be grateful.—INQUIRE.

HORTICULTURAL AND COTTAGE GARDEN SOCIETIES.

"D., Deal," writes almost despairingly. "I think it becomes a question whether flower shows are increasing in favour." The position of the Horticultural extremely critical; the Crystal Palace shows don't pay; Alexandra Palace defunct. What a climax of horrors!

In corroboration, I see the County Horticultural Society nearest me struggling against difficulties which will defy the strength of Hercules to overcome should they have one or two more rainy show days; I see others which the onslaught of a single "WYLD SAVAGE," if he were so inclined, would suffice to topple over, and which a single good downpour on their show day would certainly cause to melt into sily nothing. Such is the moribund condition of "horticulturals." At the same time I see numerous cottage garden societies cropping up around like so many Mushrooms, and most of them too, I fear, doomed to the same ephemeral existence.

Now there must be a reason for this which I think it is not hard to discover. The mischief is done by the frequency of those monster *al fresco* entertainments (not flower shows) which necessitate a great outlay, the only chance of recovering which is by attracting gate money. Yes, gate money has a good deal to answer for. It has ruined legitimate horse-racing and honest pedestrianism; it is in a fair way to ruin flower shows.

A horticultural society is in a poor way whose existence depends upon next show's gate-money; and that is the case with most. For the people who attend flower shows, because they love flowers and wish to encourage improvements in horticulture, are the few; the many who perhaps do not know the difference between a *Rosa* and *Chrysanthemum*, certainly not between a *Begonia* and a *Cactus*, go there because it is "the thing;" and their first question is about the band—Coldstreams, Black Watch, or Marines? and the flowers are voted a bore because of the awful crush, and the tent where fees are sold is abundantly patronised, and parasols are furled or unfurled on the approach of friend or foe, and the usual round of fashionable small talk and byplay is gone through, and at four o'clock the shilling folks! and then exit Sir Eugenius Broadacre and all his tribe. So the grounds are surrendered to the shillings, many of whom would give their ears to know how to grow just half a dozen *Roses* in that pecky bit of a back garden; and then at six in rush the expennies, most of whom do really love flowers. But it is getting dusk, and the best of them are being removed, and many of the cut blooms are faded, still the great unwashed enjoys himself after his kind, and lastly "darkness sheds her mantle o'er the scene;" and if the show takes place at Oxford or Cambridge, the porter rings his bell, he walks his round, the mob flees before him; he locks the gates (curtain fall). But this is the fair side of the picture. The day has been fine; gate-money by batfals. Hurrah for the society! lots of money for the prizes next year! and everybody so pleased.

Is there not, however, another side? Yes, a wet day—all those tents are hired, that band came from London (or Plymouth), and does not play for nothing; those flags are borrowed for a "consideration" those gardeners and under-gardeners love wages, those gate-keepers are not above taking fees, those helps enjoy bread and cheese with beer, the Committee cannot stop on the grounds all day without something to stay their stomachs, nay, even those reporters are equal to taking a snack, and the bell-ringers (I had almost forgotten them) are a thirsty lot, and have an itching palm besides, and—and—and, in fact there is no end of petty expenses; and nobody came but judges and exhibitors, and just a few—a very few, persons who love flowers; and we shall be out of pocket this year, but better luck next time. And the end is that the subscribers, who are chiefly those that do love flowers, get

tired of giving their money year after year to pay for something that they do not love, and droop, and droop, dwindle, dwindle society—subscription to pay deficit among committee, and 'tis no more seen, and all for lack of gate money! A year or two hence a plucky secretary will get together another committee, and another society will be set on foot, and if the same rotten staff be relied on, the same course pursued, result will be another failure.

Now, let it not be supposed that I object to *al fresco* fetes in themselves, or occasional gala days, or to those terrace-recreant amusements which in many instances follow the departure of the upper ten thousand, or even to that moderate indulgence which helps the licensed victualler to feed and clothe himself and family. I do not. But I do object to that enormous annual expenditure, which the certainty of large receipts at the gate alone can justify, and to which the money paid away in prizes and in legitimate expenses bears but a small proportion.

If what I have written be a true picture of the state of things in some of our county horticultural societies, it is a *fortiori* true of cottage garden societies, which, in their humble fashion, seem somewhat inclined to ape their betters, and the result will be the same.

What, then, is the remedy? In what follows I shall confine myself entirely to cottage garden societies, and to what I think would be best for them.

First, Let them take for their motto "Union is strength." Secondly, Let them keep steadfastly in view the real objects of the society. Thirdly, I would say to them, Multiply your local shows for garden produce, minimise your expenditure on fetes.

1, "Union is strength." An instance in point: The annual musical festival of the three choirs (Gloucester, Worcester, Hereford) is a well-known fact. Each festival is perfectly independent of the others—a healthy rivalry exists between them. Each conducts and pays for its own particular festival for the same object. This festival has lasted (I write subject to correction) above a hundred years, and at all appearances is likely to last another hundred. Let three cottage garden societies, established in three different country towns, combine in a similar manner, and I believe that similar results would ensue.

2, "Keep steadfastly in view the object of the society." This I take to be the improvement of gardening by promoting a healthy competition among cottagers. One instance: In my own neighbourhood the poor have been in the habit of cultivating one particular main crop of Potatoes from time immemorial. This Potato is extremely liable to disease, being a very late sort, and change of seed being in many instances impracticable, the kind seems to be wearing out. It is neither so large nor so good as it used to be. What, then, should the society do under the circumstances? Why, clearly try to introduce some better varieties. There are plenty which may with truth be called poor man's Potatoes, notably Paterson's Victoria, Red-skin Flourball, Brownell's Beauty, Snowflake, &c.; at any rate, they suit our soil. They may be put in fairly early, and dug early, and so escape disease. I take it, then, to be the first duty of the society to sell to the cottagers at a very low rate seed of some such Potatoes as I have mentioned, to distribute printed instructions for preparation of seed and cultivation, and lastly to give prizes at their local shows for the best produce. The result would be, that in two or three years the above-mentioned first-class Potatoes would be universally grown by cottagers; and should any new variety, such as Sutton's Magnum Bonum, prove itself to be equally useful, it should be the duty of the society to see carefully to its introduction. In this way the funds of the society would be most usefully employed; and whereas the poor man—who now gives, say 9d. a stone for his seed—cannot be expected to give 8s. for Red-skin Flourball, the society—by taking a quantity at the beginning of the season, and by distributing its printed instructions—might sell at a low price, and ensure the proper cultivation of what would be in the future an inestimable boon to the poor man.

3, "Multiply your local shows for garden produce. Minimise your expenditure upon fetes." Annual fetes are so expensive that few societies can afford to have more than one show a year. This one show does not give sufficient opportunity for exhibiting the earlier and the later kinds of garden produce. A middle time is usually chosen, and the consequence is that many important classes for which prizes are offered go unfilled or very inadequately represented. I would have, then, in each society two inexpensive shows at least in each year. One I

would call the Currant and Gooseberry Show, which should take in the earlier Potatoes, Roses, and the fruits most grown by cottagers; the other I would call the Apple and Pear Show, to be held at the end of September or beginning of October, by which time all the second early and late Potatoes should have been dug and stored.

An inexpensive show could not be held *al fresco*, but it should be held in a covered market or large public room. It would be visited by all the real gardeners of the neighbourhood, and the receipts at the doors (for gate money is a necessary evil) should go to cover the expense of the visit which our cottagers would pay to our neighbours' triennial gala; for I propose that each of the three societies whose union I contemplate should hold once in three years a horticultural fête, when the gentlemen in the neighbourhood would turn out the contents of their conservatories, and when bands, and flags, and dancing, and other attractions might be hung out to their heart's content. And in order that our cottagers may not think that they are the only people who can grow Potatoes, and that they may gain wisdom by the sight of what their neighbours can do, and that they may have a real good outing (which to them means a day's pleasure), part of the funds of the society should be each year set apart to pay the travelling expenses only of all cottage exhibitors who have taken prizes or whose produce has not been condemned by the judges as inferior and unfit for exhibition. I should expect that under this arrangement a very large number of the members of the united societies and their friends would be induced by fellow feeling or curiosity, or perhaps even by cheap railway fares, to support the triennial fête held by their neighbours from year to year.

Thus, I imagine, might be established what I began with—union, competition, economy, and perhaps permanence.—
SEXES CORCUES.

MAIDEN-HAIR FERNS IN WATER.—It is often a matter of annoyance in arranging cut flowers in glasses that the Maiden-hair Ferns do not last well. I find that the fronds stand well if a greater or less quantity of the pinns are submerged in the water. Doubtless the slender rachis in this family of Ferns does not supply a sufficiency of moisture to the pinns, but when some of these are also placed so as to absorb water, the lasting qualities of the fronds in a cut state are much enhanced. The plants used for cutting from are wintered in a temperature ranging generally from 45° to 50°, the plants being kept pretty dry all through the autumn and winter.—R. P. BROTHSTON (in *The Gardener*).

THE ROYAL HORTICULTURAL SOCIETY.

TO THE EDITOR OF THE TIMES.

SIR,—I fear that the letter from the Secretary of the Royal Horticultural Society in your paper of Friday will cause some disappointment to horticulturists, especially in the country. Having been lately in communication with very many of them, I believe it to be their feeling that horticulture is the most popular of all sciences in this country, and that horticulturists are perfectly able and willing to support a society for its promotion. A very short time back the leading London horticulturists were anxious to free the Society from the incubus of both South Kensington Garden and of the Commission of 1851, and to let it stand on its own bottom. Now, it seems we are to go back to the old story, "to make the gardens attractive to the residents in their neighbourhood and of London generally," and "the residents and owners of property in the neighbourhood" are again to be the backbone of the Society. London is a large place; there is plenty of room for two societies; might it not be well to organise a national society for the promotion of horticulture, the funds of which would be applied to strictly horticultural purposes? Dr. Hogg's letter speaks of a tenancy of the gardens up to 1892. The old saying, "Where there is a wrong there is a remedy," may not always be correct; but it does seem a wrong that land variously estimated in value at from £300,000 to half a million, bought mainly with the shillings of visitors to the 1851 Exhibition, should be exclusively used as a square for the neighbourhood and for our Committee meetings and shows, for which, though it is the most convenient situation, this convenience could not by any process of valuation be stretched to £500 a year.

There are many horticulturists through the country now collecting names of those who desire to become Fellows of the Society or of a society free from encumbrance, paying subscriptions a guinea annually. Will you allow me to beg them to confine their exertions? I cannot and will not work except as an amateur, and shall be most glad to be freed from even this

work; but let us only collect a sufficient number of good would-be Fellows, and all the rest will follow. There must be plenty of competent and energetic men, who, partly for the love of horticulture and partly for occupation and a post, would undertake to collect and cement together the material which is so abundantly scattered through the country. I do not speak without hook, being about to print in a report to the Committee for collecting guineas Fellows a long list of names, including the best-known horticulturists in all parts of England, Scotland, Wales, and Ireland, who are most anxious to have a really representative society to promote their well-loved art.

Your obedient servant, GEORGE F. WILSON.
Heatherbank, Weybridge Heath.

TO THE EDITOR OF THE TIMES.

SIR,—I regret that Mr. G. F. Wilson should have written his letter to *The Times* of the 23rd inst. without consulting his friends on the Council of the Royal Horticultural Society, among whom there are some who share his views as to the taking steps to sever the connection of the Society with the South Kensington Gardens. However desirous the Council or the Society might be of such a severance, the fact is that it is simply impossible without the consent of the debenture holders, and this consent they have refused. Is Mr. Wilson, then, prepared to run the risk of attempting to establish a rival society? The chances of his failing to do so are many, and he may injure more or less the Royal Horticultural Society and the advancement of the art which he really wishes to forward.

It is not generally known that the Society does something more than make flower shows and supply a recreation ground to South Kensington. The Scientific, the Fruit, and the Floral Committees meet every fortnight. The first is composed of some of the most eminent men in various branches of science, and the other two of leading scientific and practical horticulturists, and that they are efficiently doing work that is highly valued at home and abroad is evident from the published reports of their proceedings. The important experiments in practical horticulture that are conducted at Chiswick are, as Mr. Wilson knows, well done. What prospect, then, has that a rival society without the appliances that the Royal Horticultural has would do the work as well or better? He must be prepared with an annual income of at least £5000, besides the capital expenditure; and I ask if Mr. Wilson is prepared to find that sum. If not, it would be much better to support the existing Society.

Mr. Wilson's ideas as to the more extended support of the Society which would ensue if the subscription were one guinea have already been considered by the Council, and, subject to the decision of the annual meeting on the 13th of next month, adopted in substance; the only points of difference being as to the title of the subscriber, fellow, or member, the right of voting, and whether or not the privilege should be confined to those residing beyond a certain distance from London.

As to the value of the gardens at South Kensington, it is only fair to the Society to bear in mind that it has expended on them the sum of £73,000, and that it is principally owing to them that the land in their neighbourhood now realises the high prices which it brings. The value of the gardens is estimated at that of building land, but this is to forget the fact that to build over them would destroy the value which they as gardens create, and seriously depreciate the value of all property near them. What, for instance, would be the effect on the value of house property in Bolgrave Square if the square itself were to be built over?

The dealings of Her Majesty's Commissioners with the Society I have no right to enter upon further than to say that if questioned by proper authority I believe they will be found to have been justifiable in every respect.

I am, Sir, your obedient servant, ROBERT HOGG.
Royal Horticultural Society, South Kensington, Jan. 25th.

The following commentary on Mr. Wilson's letter is from the "Gardener's Magazine":—

"MR. WILSON has published in the *Times* and other papers a letter, in which he proposes the formation of a national society. The letter is ill-timed, and its publication so extremely injudicious that we cannot trust ourselves to say all we feel. In the first place, it suggests to the world at large that there is another split amongst the horticulturists when there is indeed no such thing; and, in truth, there has been no split at any time, however to the general public it may have appeared so. To make it appear that the house is divided against itself is bad enough; but, as Mr. Wilson has been figuring lately as a horticulturist with a bran new scheme of federation in his pocket, we should have preferred to see him show some steadfastness of character, and not display, as he has done, the shiftness of character that fits a man for leadership. Mr. Wilson professes to have formed a Committee. He has never called the Committee together, and his rash letter was written without the cognisance

of the Committee, and it demonstrates the fact that he is himself the alpha and omega of the guinea movement. To make such a proposal now is not only imprudent as suggesting the desirability of another failure—it is a breach of faith. He professes to have in his hand the promises of six thousand persons to join the Royal Horticultural Society as soon as the guinea subscription is adopted. The Council profess to be favourable to his proposals, and suggest a modification. Instead of waiting for the meeting, and then urging his case with such aid as he may be sure of if the six thousand is a fact, he plays turncoat, and "goes over" to an imaginary thing that has already been talked of so much that sober men are sick of it. He has been striving to work us all up to fever heat, and has had all the assistance he asked for from the press; and now in the columns of the leading daily paper he tamely pours cold water on his own work, and if the hissing that results disquiets him he has but his own unsteadfastness to thank for it. He was bound by all the laws as well as the courtesies of public life to discuss the matter first in the Council room at South Kensington, and in the event of failing to obtain all he demanded he could have carried his six thousand with him to the end of the world—that is, of course, provided they were willing to go with him."

EVERLASTINGS.

In making a selection of seeds these useful flowers must not be overlooked. They are effective when growing, and their flowers are valuable when dried for winter bouquets. The following are deserving of cultivation:—

Helichrysum.—Decided colours are the most desirable, such as are afforded by *H. monstrosum flore-pleno*—varieties album, roseum, atrococcineum, purpureum, and luteum; or a collection may be obtained which will include those and other shades of colour. Hardy annuals. Sow during early April in light rich soil in an open situation, the rows being 18 inches apart, thinning the plants so that they ultimately remain 1 foot asunder in the rows. The flowers upon plants treated as hardy annuals are not produced in quantity until late summer with me; but 1 sm in a high cold situation, in which the plants should be treated as half-hardy annuals, sowing in March in a gentle hotbed, pricking off the seedlings, when they have a pair of rough leaves, 2 inches apart in pans or boxes, returning them to the hotbed until established, then be transferred to a cold frame, hardening well off before planting-out in May. The plants will repay potting-off singly in small pots, from which they may be transferred to the open ground without the check consequent upon planting from pans or boxes. I have sown the seeds in rows 6 inches apart in a cold frame, keeping close until the seedlings appear, and then admitting air freely, having them well hardened-off by the second or third week in May, and then planting-out. In that way they answer well, but the autumn being wet the flowers are not nearly so good for drying as those produced earlier. 2½ to 3 feet.

Xeranthemum annuum flore-pleno, purple, and its white variety album, are very showy and desirable for drying, requiring the treatment of *Helichrysum*.

Acroclitium roseum, and variety album, are half-hardy, requiring to be sown in a hotbed during March, pricking-off the plants when large enough to handle, and growing them in gentle heat until established, hardening well off, and then planting-out in rich light soil in an open yet sheltered situation. The rows should be 1 foot apart, and the plants in them 6 to 9 inches asunder. 1 foot.

Annubium alatum is a very pretty small white flower, requiring the treatment of *Acroclitium*, but with an increased distance of 3 inches between the rows and plants. 2 feet.

Rhodanthe maculata (rose, yellow centre), and its varieties atrosanguinea (crimson); alba, the loveliest, having a fine silvery appearance; and *R. Manglesi* (silver and rose, with yellow centre), are really charming for greenhouse decoration; I grow three plants in a 5-inch pot, or five plants in a 6-inch pot, affording a light airy situation, watering liberally. For outdoor flowering sow during March in a hotbed, pricking-off the seedlings when large enough, growing on, and hardening well off before planting-out at the end of May, 9 inches apart in rows 1 foot asunder. 15 to 18 inches. Rich light soil.

Helipterium corymbiflorum, white, and *H. Sanfordi*, pale yellow, half-hardy, requiring the treatment of *Acroclitium*. 9 inches.

Waltia corymbosa, reddish, with yellow disc; *W. grandiflora* is perhaps the finest of all yellow Everlastings. Be careful not to overwater. The treatment recommended for *Rhodanthe* is suitable. 15 to 18 inches.

Gomphrena globosa, *vers. alba*, *aurantiaca*, *cernea*, *purpurea*, and *striata*, are tender or greenhouse annuals; their globular heads being cut when full-sized and dried are very useful, the plants also when growing being very effective. Sow during March or early April in a hotbed, pot the plants singly or three in a pot, and grow them in gentle heat, shifting into larger pots as required, giving single plants 6 or 7-inch pots, and trebles 8 or 9-inch pots. Rich turfy and gritty loam will grow them well. Place the plants in the greenhouse in June, affording a light airy situation. 18 inches to 2 feet.

Statice Donduelli, pale yellow or sulphur, and *S. Thounii*, blue and white, are very pretty. Sow early in March in a hotbed, pot-off singly in small pots, growing on in gentle heat, removing to a cold frame in May, and planting out in an open situation in rich light soil at the end of that month or early in June; or the plants may be shifted into 5 or 6-inch pots, and given a light airy position in the greenhouse, where they will flower to a late period. They are half-hardy perennials, but are best treated as annuals. Plant outdoors 9 inches apart in rows a foot asunder. *S. sinuata* (blue) and *S. spicata* are both half-hardy and useful; the latter, rosy pink, is fine for rock-work. The flower spikes should be cut when a majority of the flowers are expanded.

All Everlastings for drying should have the flowers cut, unless otherwise stated, before they are fully expanded, cutting with a few inches of stalk, and be tied in little bundles for convenience of suspending in any dry place, or they may be placed thinly on shelves in any dry airy house, as that of a vinery from which the Grapes have been cut. The flowers must not only be dry after they are cut, but be perfectly so when cut; for if cut wet, or if they become damp afterwards, they will certainly decay.—G. ABBEY.

OUR BORDER FLOWERS—FLEAWORTS.

This is a rather numerous family of border plants. With this genus as with many others, some species are cared for and sought after, some are neglected or cast to one side. We do not entertain the idea of cultivating all the plants enumerated in closely packed columns, for to do that we should require a farm of no small dimensions; yet many border plants are so charming that we are constantly adding to our numbers. Some of the race in hand ought to occupy prominent places in borders and on rockeries. According to English botany we have a representative in this family, but I think its name admits of a doubt—*Erigeron canadensis* sounds to me rather un-English, yet it is worth retaining.

The Fleaworts are a large and widely distributed family, inhabiting many parts of the globe, and soon make themselves at home with us in our borders. They are not particular as to soil or situation, but must have light and air. Some of them are tall-habited plants, while others are of small stature. *Erigeron glaucus* is of compact dwarf habit, and is an acquisition to any rockery or border; its pretty blue with yellow-centred flowers have a pleasing effect. Some of the species are said to be possessed of properties which drive away gnats and fleas. *Erigeron acris* is said to belong to our own flora; *Erigeron alpinus* and *E. uniflorus* both hail from Scotland, and are well adapted to the rockery and the border. They in a great degree resemble *Aster alpinum*, with which they are sometimes confused. *E. Villarsii*, *E. grandiflorus*, *E. purpureus*, and *E. serotinus*, are the kinds most met with in cultivation. There are many others of the family that are worthy the cultivator's notice. They will bear a good share of rough usage, and are easily increased by division in spring or autumn.—VERITAS.

GYMNOGRAMMA PERUVIANA ARGYROPHYLLA.

THE Gold and Silver Ferns are considered by many to be entitled to be placed in the front rank of their race, and amongst the many species and varieties now in cultivation there is perhaps none more generally admired than the plant under notice, *Gymnogramma peruviana argyrophylla*. The broad gracefully arching fronds, covered densely below and above with a powder of snowy whiteness, attract the attention of the most ordinary observer; nevertheless this Fern, though of easy culture, is in many cases devoid of that luxuriance and silvery whiteness which characterise a really flourishing plant.

The treatment under which I have found it to succeed best is very simple. Supposing we commence with a young plant in a 3-inch pot in March, it will then in all probability require

a shift into a 7-inch pot, using a compost of two parts of fibrous peat, one part of sphagnum rubbed through a sieve; the other part to consist of friable loam, coarse silver or river sand, charcoal broken small, and a little well-decomposed dried cow manure. Mix the whole well together, and in potting be sure and drain efficiently, and keep the crown well above the soil, and stagnation of water in the heart of the plant will thereby be avoided and finer fronds will be produced. Using such a porous compost renders liberal supplies of water absolutely necessary, applying it close to the edge of the pot, so as to prevent the farina being washed off the young fronds just emerging.

The plant must be placed in a position where it is not likely to suffer from condensed moisture dripping from the roof of the house, and it must not be syringed. It luxuriates in strong moist heat and a light position. It will bear more direct sun than most Ferns, moderate sunshine enhancing the richness of its silvery fronds. In June the plant should be moved into a 10-inch pot, using the same compost as described above, well warming it previously, and, if a suitable temperature is afforded, a plant 4 to 5 feet across will be the result.

It is during the winter months, however, that the plants show a tendency to look woody, and many are annually lost because a sufficiently high temperature cannot be maintained. Less than 55° nearly always results in the loss of the plant. If a low temperature is the only alternative, keep the plant in the driest and warmest part of the house, giving only sufficient water to keep the fronds from shrivelling. In a warm stove the plant is thoroughly at home, and requires moderate supplies of water throughout the winter.

A porous soil, plenty of water during growth, a moist tropical temperature, and warm winter quarters are the chief requirements of this beautiful Fern.—A. W., *Lincoln*.

LONICERA FRAGRANTISSIMA.

A HONEYSUCKLE in full bloom in midwinter is not a common sight, yet a fine plant some 10 or 12 feet high of *Lonicera fragrantissima* is now full of flowers, which are most valuable for cutting, the delicious perfume being quite equal in its delicacy and sweetness to that of the Lily of the Valley.

This Chinese Honeysuckle proves to be a very valuable evergreen shrub, the short-jointed sturdy growth being clothed throughout the year with deep green foliage, handsome in form and of great substance. Although the mild weather has caused its flowers to appear a few weeks sooner than usual, yet it may justly be termed the winter-blooming Honeysuckle, as it generally comes into flower in February when planted in a sheltered situation. So highly do I esteem it that I intend planting several of it in different situations, so as to prolong the season of its flowering as long as possible.—E. L., *Sussex*.

BUSH ALLAMANDAS.

EVERYONE who has seen these magnificent free-flowering plants growing in the stoves of Wimbledon House, and alluded to by Mr. Ollerhead on page 6 of the present volume, must have been struck with their great beauty; but it is not all who can afford such an expanse of roofing to allow Allamandas to display their natural beauty, and such persons must be content with growing a few plants in pots, which, as Mr. Ollerhead hints, often find their way to our public exhibitions. No stove plant is more worthy of a place there, for its large yellow trumpet-shaped flowers are very striking; but the plants are so often seen trained so closely to a balloon trellis that they present a stiff and formal appearance. The mode of training I adopt is a bush-like form, and plants so trained present a very satisfactory appearance, showing the flowers off to great advantage.

The present is the time to commence training operations. My usual mode at the commencement of the new year, and after the plants have become dry and well ripened, is to cut away all green shoots, and prune well into the ripe wood. Should the plants require repotting, which is usually the case, I place the ball in tepid water to ensure its being thoroughly moistened, and after it has drained, a portion of the old soil is removed, and the plant is repotted, using good fibrous loam with an admixture of sand. I then tie each shoot down as close to the rim of the pot as possible. When all are brought down they bear a close resemblance to a bundle of dead sticks; but this low training induces the shoots to break well back. When all is finished I place the plants as near the glass as possible,

and the young growths are both shorter-jointed and stouter than when placed a greater distance from the glass. The after-training does not entail much, if any, more labour than the ordinary method of tying to a trellis. As the growths extend some sticks are placed in the pot at proper intervals, and to these the growing shoots are secured, and a bush-like form is attained precisely in the same way as with Heaths or other hardwooded plants.

A plant thus trained of *Allamanda Hendersonii* was last season over 4 feet in diameter, and loaded with its large yellow flowers from June till October. It would have bloomed much longer only that I ripened it off to commence training early for another season. The *Allamanda* requires plenty of water, and delights in occasional doses of manure water while growing.—J. W. MOORMAN.

[The plant referred to was exhibited at Wimbledon, and the mode of training was generally admired.—Eds.]

THE APPLE ELECTION.

I SHOULD like to make a suggestion as to the arrangement of names, &c. In reading over a list of Apples in the English edition of M. de Breuille's "Fruit Trees," I found an arrangement there which I think with a little alteration would be the very thing required. *Summer Apples*—Dessert, Kitchen. *Autumn Apples*—Dessert, Kitchen. *Winter Apples*—Dessert, Kitchen.

In M. de Breuille's list there are less than six Apples named for the summer, and a great many more for the winter, but I propose to confine the number to six in all classes, to be mentioned in the order of ripening.—AMATEUR, *Gloucester*.

[Many correspondents have urged an election of Apple trees. We cannot undertake to arrange returns from the fruit-growers of our islands, but if anyone will undertake the task we will aid him in every way within our power. Will our correspondent oblige us by a list of the fruits he has elected for Gloucestershire?—Eds.]

ROSE-GROWING IN YORKSHIRE.

A YORKSHIREMAN is always jealous for the honour of his native county, not less so a Yorkshire woman. I quite believe that the brother of "WILD SAVAGE" will not find his Roses flourish under the "depressing circumstances" mentioned in your number of 25th January; but allow me to say that all Yorkshire is not so unfortunate, as it comprises many soils and many climates.

Here, near Hull, one mile from the east coast, our inland friends pity us for what they unwittingly designate our "fearful climate." While I walk round my garden in the midst of my Roses, in bloom early and late, and whilst admiring my favourites I can afford to laugh at my friends, for who amongst them, down to rosy Hertfordshire, can show finer blooms than I? whilst I enjoy them none the less because they are most of them raised and nursed by my own hands.

I do not feel at all inclined to tell "WILD SAVAGE" that he knows nothing whatever on the subject of Roses, but I do maintain, from my own experience, that Teas and Noisettes should be as little moved as possible in this district. The soil is clay and not a very kindly one, the winters very mild, the springs very cold and dry with frosty nights and hot sunny days. These are what we have to guard against, and Teas as well as other kinds of Roses so often die if planted in the spring, and are checked if moved in the winter, that I avoid the risk as far as possible. The only protection I ever give is a little shading with a few branches of furze to a few of the more delicate varieties, and I think of this the less the better. My garden is not large, I think I should not love it so well if it was; but I can safely say that the winters have never killed me either a Tea or Noisette Rose. The only Roses I ever lost from frost were one or two of the old Bourbon Charles Duval in the winter of 1860-61.

I quite agree with "WILD SAVAGE" in thinking that Tea Roses do not do well under a wall nor yet on it; indeed, so sure was I that nailing to a hot wall did not suit them, that I had mine unsafened and staked some years ago, since which they have done much better, and it was very satisfactory to me to find my own views corroborated afterwards in the pages of this Journal. There is no place where they thrive as they do in an open though sheltered border. I have all my Roses manured with a Jewish hand as early in winter as I can tolerate

to deface my borders; the manure is dug-in in the spring, and if the summer is dry an occasional thorough watering is given and thankfully received.

If my small experience is worth anything, let me strongly urge the desirability of growing all Roses, but more especially Teas, on their own roots. They will require well staking at first, but in a few years many of them will be strong enough to withstand the fiercest gales without injury, whilst their neighbours on unsightly standards will be knocked about or very likely lose their heads altogether, whilst as for the blooms there is no comparing them. I have only one excuse to offer for presuming to give an opinion in company with so many authorities on the inexhaustible subject of Roses, and that is—**Success.**

SOME SPECIES OF PRIMULA.—No. 4.

PRIMULA DECORA—COMELY AURICULA.

Its specific characters are thick smooth leaves, acutely serrated; calyxes clumpy, and pedicels longer than the scape. "This is nearly allied to *Primula villosa*, but we think it is specifically different. The serratures of the leaves are larger and much fewer, being usually about four on each side, and occupy the sides of the leaf only, leaving the apex pointed and entire; or, in other words, the terminal tooth is larger and more acute than the others.

"In the late Mr. Zier's 'Herbarium,' now in our possession, is a specimen of this plant from the Kew Gardens, where it was then called *decora*, which name we have adopted, being convinced that, although frequently taken for *glutinosus*, it is quite distinct from that species, which has nearly or altogether sessile flowers, and narrow, minutely-sawed, and clammy leaves.

"We are not acquainted with the country from which it came. It was communicated by N. S. Hodson, Esq., of the War Office.

"Flowers in April. Is as hardy as the common Auricula, and requires the same treatment."—(*Botanical Magazine*, t. 1922.)

ANTS AND TOADS.

"Go to the ant thou sluggard, consider her ways." I am not going to preach a homily, that is not my forte; but observing a few days ago some ants very busy on a young shoot of a Grape Vine, I was induced to watch their movements, and saw that they were collecting the small crystal globules which had exuded from the Vine shoot. It did not appear that they were feeding on them, but carrying them away most likely to feed their young. I observed one in particular, which was fearful of losing the precious morsel, reversed its position on the stem, so as to more securely hold it. In a short time all the almost infinitesimal globules had disappeared. I collected a few to ascertain if they had any taste, but they were as tasteless as homœopathic globules, but rather gummy, and did not dissolve on the tongue. From this and my previous experience I do not think ants injurious to the plants which they visit. They are seldom seen on plants unless there is food of some kind for them, aphid, scale, or mealy bug. After all

the globules had disappeared from one Vine the ants took up another, and so on through the entire length of the house.

While on the subject of gardeners' friends I may instance the sagacity of a toad which came under my notice. Some sixteen years ago, when living in Derbyshire, some of my assistants drew my attention to the actions of a toad in a pit which had been recently cleared of Melons. I saw that it was snapping up woodlice, and it poised its head as instinctively as a terrier dog at a rat's hole. I thought I would try its insect-devouring propensity on larger game, procured some fat well-fed cockroaches, and tossed them down before the gentleman in brown. After cunningly eyeing them for a second or two, "snap," and they were gone. Now, for sport, I thought I will see if toads are to be caught with bait. I then tied a piece of thread to one, threw it down near the devonour, and "snap" again. I then drew it 4 or 5 inches, when the toad finally ejected it. I then tried it without the string, but the toad was too wise to take that. I put down a fresh one; that was soon put out

of sight. If this does not show sagacity of a character higher than we give such things credit for I am mistaken. It may not be generally known amongst gardeners, but toads slough or shed their skins annually like snakes. My attention was drawn to the action of one in a cucumber house scraping alternately with its paws over the back of its head, similar to the action of a cat when cleaning itself. On close examination I saw that it was completing the removal of its old coat. From that time I have watched their varied actions with great interest, and keenly appreciating their services.

Many are the prejudices against this useful creature, one in particular I will mention. An old gentleman, whom I succeeded in a situation, was kindness itself, and would not "heedless tread upon a worm," was of opinion that toads snuck Strawberries, and if he found one inside the garden walls would carefully take it up and convey it to the outer world. No doubt many of the readers of this may have heard of similar prejudices; but if the habits of these minor

Fig. 10.—PRIMULA DECORA.

subjects of creation were more closely studied, many an instructive lesson would be learned.—J. GARD, *Thorndon Garden, Brentwood.*

THE PROPHET ELM AT CREDENHILL COURT, NEAR HEREFORD.

THE common English Elm—for height and size, for grandeur of form, and for majestic growth, combined with lightness and beauty—has few competitors. It gives to our parks and pleasure grounds grand avenues and noble groups of trees; it encircles our home landscapes, adorns our houses, and gives everywhere a shade in summer that adds greatly to our personal enjoyment, and make it perhaps, in its homely and domestic associations, the most general favourite of all our large trees.

Many superstitions are connected with the Elm, so that each of them may be considered to be a "Prophet." Thus Cardanus says, "The leaves of an Elm tree falling before their time do foreshew a murrain or death of cattle." There is a peculiarly-formed Elm in Hampton Court garden known as "King

Charles's Swing," of which it is safely said that whoever sits in it long enough is cured of the headache.

The Prophet Elm at Credenhill Court is worthy of note from its name. Whenever a death is about to take place in the

family of Eekley (the owners), it is said to be foretold by the breaking-down of a large bough, and the most convincing (?) instances are given of the correctness of these occurrences. The "Prophet" is a fine tree, and grows in the garden on the

FIG. 11.—PROPHET ELM AT CREDEHILL.

western side of the house. It presents a fine, tall, straight bole, which measures 16 feet 9 inches 3 feet from the ground, and the trunk rises some 40 feet before giving off any branch of importance. The "Prophet" is said to contain 400 cubic feet of timber, and its special peculiarity rests in its having two important remains of branches below the foliage, the first

being 27 feet from the ground. The "Prophet" is probably not much more than one hundred years old, as Elm trees, and indeed all other trees, grow faster at Credenhill than elsewhere in Herefordshire. The height is about 110 feet, and there is every reason to believe that the tree is very free from decay.

In reply to some queries the Rev. C. H. Bulmer, rector of Credenhill, has obliged me with the following answer:—

"The Prophet is undoubtedly in magnificent health, and bears his years—certainly over a century—extremely well. Indeed were it not for the occasional inroads into his constitution incurred in the faithful discharge of his prophetic office, without doubt he ought to last well through another century. The tree may be said to possess more of a family than local reputation. The superstition is as follows: When any branch of the old Elm falls, one of the members of the Eckley family is supposed to hear in the crash of the ponderous bough (and on account of the close contiguity of the tree to the mansion it is very easily heard) his own death knell. On two occasions I can bear personal evidence to the prophecy being singularly fulfilled.

"The Eckley family came into possession of the Credenhill estate, which was purchased from Henry Grey, eighth Earl of Kent, in a very curious manner; at least so says tradition. Edmund Eckley rode a race on relays of saddle horses to London against the owner of the Foxley estate, the ancestor of the late Sir Uvedale Price, the well-known musician, botanist, and landscape gardener, and arriving first bought the estate. It may carry some little interest with it if I mention that my predecessor in this living, and the former owner of the estate, the Rev. John Eckley, told me that this Sir Uvedale Price of Foxley (who was not only a near neighbour, but also a very intimate friend) himself superintended the pruning of the tree in its first stages of growth, which may partly account for its unusual altitude and dimensions, if hardly for its prophetic eccentricities. Sir Uvedale was also neighbour to and a very intimate friend of a still more distinguished man—Andrew Knight of Wormesley Grange."

There are many remarkable Elms in Herefordshire, though London, in his "Recorded Elms," only mentions three trees in the whole county. The most remarkable are the Rotherwas Elm, the Kingsacre Elm, the Stretton Rectory Elm, the Wormbridge Elm, the Holme Lacey Elm, the Much Marcle Elm, the Ridgemoor Elm, The Westhild Elm, the Castle Green Elm, and Cathedral Clove Elms, Hereford; the Hill Court Elms, and the Ross Churchyard Elms. At the latter place two young Elm trees have sprung up within the church, and have been allowed to remain there. They are suckers from the roots of the tree which grew on that side of the churchyard, cut down many years since. They are said, by the man who shows the church, to grow in the pew in which the "Man of Ross" was accustomed to sit, and thus do reverence to his memory.

DARLINGTON GARDENERS' INSTITUTE.

At the meeting held in the Institute on January 18th an interesting and able paper on British Ferns was read by Mr. Harrow.

After a few introductory observations Mr. Harrow proceeded:—The study of Ferns, even if confined to British Ferns, opens out an almost inexhaustible field of study and observation. It is well known that the coal beds of this country, and especially of this county, are composed in a very great measure of the various species which at some remote period flourished luxuriantly in this island. Sir C. Lyall, speaking of one of those gigantic Tree Ferns found in the coal beds near Newcastle, says that the trunk measured 5 feet in diameter, and must have been between 40 and 50 feet in height. From this example we may see how greatly the Fern has assisted to develop the commerce of this country, and how much we owe to it. Though we do not now possess the gigantic Ferns of New Zealand or the Tropics, it is probable we have as great a diversity of foliage and as many varieties in the British Isles as can be found in an area of similar extent in any part of the globe.

Ferns differ from flowering plants both in the mode of construction and growth. If we examine the base of a leafstalk of a tree we shall find a bud, which if undisturbed will produce a bunch or cluster of fruit next season. There are no such buds in the axils of Fern leaves, not even in those of the Drake, though the latter is peculiarly tree-like in growth. The upward growth of the Fern consists of a process of unrolling, expansion, and maturation of the leaves and stems. All the Cryptogamia are destitute of flowers; that is their most noticeable distinction, unless the fertile fronds of the *Osmunda regalis* be so termed. But although destitute of flowers they are far from being destitute of beauty. The graceful forms of the fronds and their delicate tracery, combined with loveliness of colour, make them objects of our admiration. The number of British species is said to be forty-six, but what a number of varieties they present in forms differing from their types or what we call types. These varieties number at least five hundred. Mr.

Sim of Foot's Cray in Kent enumerates in his catalogue 365 British species and varieties. The varieties of Hart's-tongues are about one hundred. Some are tasselled and fringed, others resemble stag horns, frills, fans, &c. There is scarcely a species of British Ferns that does not show some varieties crested or frilled; this I consider a substitute for flowers, and certainly the variations add much to their interest and beauty. Few can look upon *Lastrea Filix-mas cristata* or *Athyrium Filix-femina* well grown without admiring them. The leaves of other plants are varying in their outline to a great extent, but those of the Fern are as fantastical, changeful, and varying as the anthers borealis. No one can thoroughly enjoy or understand Ferns unless he has hunted for them in hedgerows, woods, and amongst rocks, rivulets, and waterfalls. I have found *Scolopendrium crispum* in the wood opposite Gainford, and some peculiar sports in the same place and also at Richmond. But the finest *Polystichum aculeatum*, Lady Fern, and *Lastreas* may be met with in the woods near Coxwold and Ampleforth. The *Polystichum* seems to be quite distinct from those growing in this part; the fronds are much finer, and the colour much brighter. It is interesting to notice the different varieties of the same species growing in different localities. For instance, the *Scolopendrium vulgare* found at Richmond is distinct from that which grows west of Barnard Castle; the former being quite undulated, while the latter is rigid and straight. *Blechnum spicatum* (*B. boreale*), abounds near Barnard Castle, but it is not found at Richmond. In the crevices of the old bridge at Richmond *Cystopteris fragilis* is found, and *Asplenium Trichomanes* in the Abbey Bridge near Rokeby. At the village of Borton, not a very likely locality, I have found *Polyodium vulgare*, *Asplenium Ruta-muraria*, and a *Trichomanes* growing on the old walls.

With regard to the cultivation of British Ferns, I think many cultivators err in their treatment of them during the winter months by allowing their crowns and roots to become dry as dust, alleging as their reason for so doing that moisture may stimulate them into growth at a time when they should be at rest. I differ from that opinion, and think that if kept in a temperature of 40°, moderately moist, so that the crowns and roots never become quite dry, with as much air as possible (except during frost), they will form good crowns and handsome plants, and be a source of pleasure and satisfaction to the cultivator. As to the deciduous kinds, not having had so much experience, I hesitate to offer a decided opinion as to their cultivation. I hope, however, the discussion of to-night will elicit some good hints on it. It does look something like ingratitude to turn out in the cold these plants which by their beauty have given us so much pleasure in summer. It is likely that, accustomed to the protection of glass, they may be slightly tendered, and may not make such good roots or crowns in the open air. Mine are kept in the house, and I shall be glad at the proper season to show them to any wishful to examine them. Mr. Harrow, in conclusion, said the great principle of Fern-growing was to imitate as closely as possible the conditions under which they are found in their natural situations.

DOING AS HE WOULD BE DONE BY.

We have great pleasure in publishing the following communication:—

The conduct of an old customer of ours—who succeeded his father, after many years of business together—has been so exceptionally large-minded, and so thoroughly, I conceive, such as an Englishman in business ought always to be, that I trust you will consider the account of the transaction worthy a place in your columns.

You are no doubt aware that of late years, through the wild competition in the seed trade, it has been the absurd custom for the firms to sell Peas, Beans, and all kinds of seeds, long before they can possibly know what the harvest will produce, at the most speculative and often ridiculously low prices in the summer and autumn, so that—as in this year of a generally deficient harvest—Peas, Beans, and seeds have been sold in the summer, and have to be delivered at prices considerably below what they have to be purchased at. Whether the seed-merchant loses by it or not, of course the goods must be delivered at the agreed price; while in an abundant year—if the seed, &c., has been purchased at more than the season value—the poor seed-merchant must reduce his price to that of the season. His bargain is but a poor one in either event. Legitimate trade is thus seriously damaged and degraded.

And now for the case of our old customer. He had bought of our traveller, very cheaply and fairly at an agreed price, certain Peas last autumn. The harvest has been deficient, and the Peas he bought are worth double what he agreed to give. In settling his quarterly account he thus writes, January 10th, 1877:—"As your imperfect knowledge of the value of the Peas

in the autumn caused you to put too low a price on them, I see no reason why I should derive an advantage from the circumstance, and therefore I request to be allowed to pay the worth of them. I have added £— to your account."

I think you will agree with me that this is a fine spirit rarely to be met with, and deserving of record; and I would add that if all our business were carried on upon such honourable, liberal, and high principles as those displayed by our old friend (who little thinks that we are writing about him), trade would be far more honest, agreeable, and profitable.—A SEED-MERCHANT.

A GOOD OLD ROSE.

A ROSE that is remarkable for the abundance and excellence of its flowers when flowering with and among others of the most select sorts; for its earliness and lateness, or rather its almost perpetual property of flowering; for its free, abundant, and wonderfully robust growth; for the large size and elegant form of its foliage; for its adaptability to every form of culture under which a Rose can thrive, and to every style of training, to every position or aspect, must perforce make its way into general favour. Such a Rose have I. Among standards none are in such rude health, have such rampant growth, are clothed with such handsome foliage—green and glossy even now in midwinter—or bear such huge clusters of large flowers all through summer and autumn. Among climbers none are more vigorous or cover a large area of wall space more quickly, continue in flower so long, or give fine flowers upon all aspects, north as well as south, as it does—once plant of it upon an open west wall even now in January having several large fully-expanded blossoms which would not disgrace a summer bouquet; moreover it is equally "at home" upon stocks of all kinds or its own roots. Who can tell me the name of my Rose, or of any variety which they have found equal to my description? We have had a Rose election which has done, and doubtless will continue to do, much good. Let us now see if we cannot find out a few kinds of superlative merit in every respect, and which are therefore as valuable for covering the sides of a house, for planting in the Rose garden, for forcing and general pot culture, as for furnishing cut flowers for that stand of any number with which we always win the first prize and cup! Have we half a dozen such? I trow not. I have only one. Who can me tell its name?—EDWARD LUCKHURST.

SPECIAL FLOWER SHOWS.

UNDER the above heading at page 61 of this volume of the Journal, Mr. Douglas quotes a passage from the Rev. J. B. M. Camm's remarks at the late Rose conference to strengthen his argument that other varieties of florists' flowers besides Roses have, and do still, support distinct shows. Alas! that such lovely, and I thought universally popular, flowers as Carnations and Picotees, &c., should need any special pleading. To the following sentence, which has a second time appeared so prominently before the public, I must be allowed to demur, as being contrary to facts:—"Country Rose shows generally betray failure in some form or other; Hereford, for instance, where the largest balance ever forthcoming was 4d." These words, which I well remember were spoken by Mr. Camm in that happy jocular vein his friends know so well, and with which our cloth, from honest old Latimer to Sydney Smith, have occasionally refreshed themselves and others; but by which strangers and others not quite so conversant with my clerical brother's hard-hitting punishing phraseology, may very easily be misled.

Amidst the wreck of falling Rose shows I turn with pleasure to the last two published reports of the West of England and Hereford Rose Show, which lie before me, and find that in the past two years the Treasurer's balance in his favour to be respectively £3 8s. 2d. and £14 10s. 6d., while last year's prize list (including cups) was nearly £190.—HEREFORDSHIRE INCOMET.

NOTES AND GLEANINGS.

IN the front garden attached to Mr. Barron's residence at Chiswick is growing a thrifty specimen of the EUCALYPTUS OBOLEPTUS. The plant has endured four winters. The extremities of the shoots have been killed during past winters, but on being pruned the main branches have grown again freely. The plant or tree has received no injury whatever

during the present winter, and is conspicuous from its large and distinctly-coloured foliage. We never saw a Blue Gum tree more hardy-looking and exuberant than this young specimen.

— THE BOURNEMOUTH WINTER GARDEN, which was recently opened, is an imposing glass structure, and was erected by Fletcher, Loundes, & Co., 13a, Great George Street, Westminster.

— WE are informed that the HEIGHT OF WELLINGTONIA at Cotlands, Sidmouth, is 42 feet, the circumference of its stem at its junction with the ground being 10 feet 4 inches, circumference of lowest branches 80 feet. The sizes of other trees which have been forwarded to us are as follows:—A tree at Kilton 44 feet high, circumference of stem 10 feet; at Poltimore a tree is 60 feet high; a tree in the cemetery at Bath is 40 feet, and one at Beaufort near Battle 40 to 50 feet.

— WE have received from Mr. Arthur Perkins, Park Nurseries, Coventry, cuttings from young VINES which were planted in May, 1875. The wood sent of Madresfield Court, Muecat of Alexandria, Lady Downe's Seedling, and Black Hamburg is exceedingly strong, also well matured, and affords conclusive evidence that Vines may be well grown in "unprepared borders." Excellent Grapes can hardly fail, being produced by canes of such superior quality. We should be glad, however, to know what Mr. Perkins means by "unprepared borders." What is the nature of the soil and sub-soil, and what stimulants have been afforded the Vines?

— AT the spring exhibition of the Royal Horticultural Society held last year at South Kensington FORCED PLANTS OF SOLOMON'S SEAL (*Polygonatum vulgare*), which had been grown at Chiswick, were much admired. This may be an opportune period for directing attention to this valuable old plant as being the time for potting the crowns for early flowering. The crowns at Chiswick we noticed the other day are just starting into growth. After being potted they are placed in a warm dark place until growth fairly commences, when they are removed to the light. It is very important as the growth advances that the plants be kept as near to the glass as possible, to keep them as sturdy as is consistent with their nature. When flowering, their delicate light green foliage and elegantly arched shoots laden with white flowers are highly effective. As arranged on stages the plants show to much greater advantage than when growing in the garden, where the flowers are necessarily much hidden by the foliage. The plant is worthy of being forced by all who possess crowns and have the means of forcing them.

—"I was agreeably surprised the other day," writes Mr. Luckhurst, "when looking over a bed of the LEAMINGTON BROCCOLI to find a goodly number of it fit for immediate use, and to see from the appearance of the remainder that a succession may be depended on from this one bed for some time to come. This early maturity is, of course, owing to the mild weather; and even in this exceptional state of things I am glad to find this excellent variety retains its peculiar property of coming in gradually, precisely as it does in ordinary seasons, when, as has already been told, I have cut from the same bed excellent heads in March, and continued doing so till June."

— WE are informed that the RICHMOND (Surrey) SHOW, which is announced to be held on June 28th, is expected to be on a larger scale than the last two successful exhibitions.

— AT all times the ORCHIDS at GUNNERSBURY are worthy of note and inspection. Even when the plants are not flowering they are attractive from their glossy cleanliness and exuberant health. At the present time the principal display is afforded by a row of forty plants of *Phalenopsis*, principally *P. Schilleriana* in variety. The plants are in baskets, and their effect, as may be imagined, is very striking. Other Orchids in flower are *Saccolabium Harrisonianum*, *Odontoglossum Bictoniense*, seven vigorous spikes; *O. Alexandrinum*, in superior varieties; *Laelia aneops Dawsoni*, so pure and yet so rich; *Cypripedium Hookeri*, fine alike from its flowers and marbled foliage; and still more beautiful in flower is *C. Parishii*. Orchids which are showing their spikes are *Odontoglossum Andersonianum*, which has perfected a wonderful growth, and will shortly have fifty-seven flowers open on one spike; *Cymbidium eburneum*, ten spikes; *Aurides Veitchii*, *Odontoglossum candatum*, &c. In this collection *Angreum seepipedale* produced seventeen flowers last year, and the beautiful *Odontoglossum vexillarium* upwards of forty flowers. Mr. Richards and his foreman have just season to be proud of

these Orchids. We never saw plants in more superb condition. The Tree Ferns at Gunnersbury are extraordinary specimens. Two of the "trees" were not less than 30 feet in height, with trunks 8 or 9 feet in circumference.

— Mr. ROGER LEIGH of Barham Court, in an address lately delivered, gave an interesting description of a system adopted in France whereby the children attending 30,000 primary schools in the rural districts receive instruction in the CULTURE OF THE SOIL. The child is shown the soil which best suits a certain plant to be cultivated; he is made to prepare it for planting, to sow it, to free it from weeds, to wage war against insects and grubs, and finally to record in his school books the advantages derived from the selection of special soils, the application of new manures and variations in the time of planting. These lessons are never forgotten, and the land allotment of the French peasant is made to produce a variety of vegetables fit for any man's table. The agricultural societies throughout France cordially second the Government in its efforts by bestowing on pupils and masters their counsel and assistance, and offering prizes for competition.

— We some time ago directed attention to the value of the common IRISH IVY for clothing the ground under trees on lawns where grass refuses to grow. How efficient Ivy is for the purpose named is forcibly exemplified in the pleasure grounds at Gunnersbury. In these beautiful gardens are several grand old Cedars (*Cedrus Libani*), and beneath them, as far as the branches extend, the ground is closely covered with Ivy, which is perfectly green and fresh under the dense shade, and adds considerably to the effect and finish of the grounds. These large circular beds of Ivy are quite ornamental and decidedly enhance the beauty of the old trees. The labour of patching the turf under trees on lawns many gardeners know to be considerable, but when once the Ivy is established only a very small amount of labour is required to keep it in order for years. The Ivy beds also add a special feature to the grounds in which they are adopted—in a word they are both effective and economical. The subject is highly worthy of being again alluded to and of being "kept in remembrance."

— AMONGST the appeals for aid owing to injury from the LATE FLOODS an application from the parishes of Billingham and Walcot near Sleaford, Lincolnshire, was read before the executive committee of the Lord Mayor's fund, stating that three thousand tons of Potatoes and Carrots and a thousand acres of Wheat had been destroyed. £345 had been raised locally and expended. The committee voted £100, with a promise of more if needed. 670 persons had sustained injury; the average depth of water in the houses was 6 feet.

— A PUBLIC GARDEN AND RECREATION GROUND for the parish of St. George's-in-the-East was opened on the 25th inst. The garden has been formed by the adaptation of a portion of the parish churchyard, under the authority of a faculty from the Bishop of London's Court, and by the purchase of a disused burial-ground adjoining the churchyard, the cost of the latter being £2700, towards which the Metropolitan Board of Works have contributed £1200. Sir James Hogg, the Chairman of the Metropolitan Board, accompanied by Mr. Ritchie, M.P., Mr. Samuda, M.P., the Lord Mayor, the Rev. Harry Jones the rector, the Public Garden Committee, and a number of the inhabitants, proceeded round the garden, and declared it to be dedicated to the public for ever.

— It is not generally known how valuable for forcing is the old hardy *SAXIFRAGA LIGULATA*. Mr. Wills has employed this plant effectively in the Westminster Aquarium, and we recently observed it flowering freely in one of the houses in the Chiswick Gardens. The plant is naturally a precocious bloomer, and at the present time is showing its flowers in the open borders. It is one of the large-foliaged Saxifrage, in this respect somewhat resembling *S. cordifolia* and *S. ovalifolia*, which flower considerably later. The flowers of *S. ligulata* are larger and altogether more attractive when they are assisted to expand in gentle heat under glass. The flowers are admirable for bouquets, and forced plants are ornamental for the conservatory during January and February.

— As an instance of additional labour caused by the LATE FLOODS may be noted the condition of the stockholes during the deluge and the cost of emptying them at the Royal Gardens, Kew. For some days and nights the cost of the manual labour in pumping out the water was, we are informed, £25 per twenty-four hours, or £175 per week. This was both

too costly and too slow for the Curator, Mr. Smith, who proposed the hiring of two of Merryweather's powerful fire engines. These were obtained at a cost of £30 per week each. These engines kept the water under, and the saving effected by their use was upwards of £100 per week. This is a striking proof of the value of steam and machinery over manual labour, as it is also evidence of the value of the services of a really competent and practical manager.

— ONE of the great ORCHARD HOUSES at SAWBRIDGEWORTH, 180 feet long, and which is filled with Peach and Nectarine trees in pots, is now a sight of great splendour. The trees are a mass of bloom, and furnish an instructive study to pomologists. This great establishment now extends over 110 acres entirely cropped with a fine stock of all kinds of fruit trees.

— A CORRESPONDENT writes to us as follows on SELECTIONS OF SEEDS—"Whilst thanking 'A KITCHEN GARDENER' and G. Abbey for their useful and excellent lists of seeds, may I suggest that they and many other contributors to the Journal would make their articles still more useful if they would make it a rule to give a short sketch of their soil, climate, and locality to prevent mistakes? Enjoying, as I do, a dry climate with mild winters but bitter springs and hot summers, I am often disappointed to find that seeds most highly recommended, but suited perhaps to a sandy soil or a rainy district, do not suit a lump of Yorkshire clay."

— "T. H." sends the following in reply to the request of "WYLD SAVAGE" on page 64:—"I remember some few years ago going to Cheddar for a day, and there I was offered some hardy Ferns by an old woman who gathered them to sell to visitors. Among them was *Adiantum Capillus-Veneris*. I should say it may still be found growing at Cheddar. There are also several varieties of hardy Ferns growing on Thapwick Heath, very probably it may also be found there."

— THE *Irish Farmers' Gazette* in alluding to Roberts' Gros GUILLAUME GRAPE, states that Mr. Roberts regards this as being quite a distinct variety from that in general cultivation, and besides producing mammoth bunches, being far more amenable to ordinary treatment. The Vine that produced the monster bunches (three of which weighed upwards of 45 lbs.) grow in no elaborate prepared compost, but in good loam, pure and simple.

— WRITING to us from Antwerp, Mr. Charles Van Geert states that the WINTER in BELGIUM has been unusually mild. They had only two nights of frost in December, and since the 26th of that month there has only been a little frost on the 22nd and 24th inst., the temperature since then being mild.

— It has been stated by Sir John Lubbock that certain kinds of APIDEEs are preserved by ants for purposes of the food afforded by a certain sweet secretion in the former, the eggs being carefully guarded and the young larvae fed and cherished until they ultimately attain their perfect form, when they served as contributions to the dietery of the ants. This singular fact was some time ago alluded to in our columns by our entomological correspondent "J. B. S. C."

— At a recent meeting of the Paris Academy of Sciences MM. Grandeu and Bontou stated as the results of chemical STUDIES ON MISTLETOE, that the composition of the stem differs essentially from that of the species of trees on which it grows. That the composition varies with the species. That Mistletoe contains much more potash and phosphoric acid than its supporting trees, and much less lime. It seems to live on the tree like a plant on the soil, and that it takes from the parts gorged with nutritive juices the incombustible matters necessary for its organisation.

— THE heavy rains may prove beneficial in a way not generally anticipated. An entomologist writes to us that "the approaching season will be notable, probably, on account of the SCARCITY OF BLIGHT or insect pests of all kinds." So far as he can judge, the destruction of insects by the heavy rains has been very great, all species suffering much more from damp than from cold during hibernation.

NOTES ON VILLA AND SUBURBAN GARDENING.

THE wet weather has hindered the progress of outdoor work, and all those who have the opportunity should make the most of every fine day. The crops which have come up are lacking the reverse of healthy, and will have to be coaxed into growth to produce satisfactory results. Owing to the inclement season

villa gardens are at present at a standstill; but as the weather changes to fine work in the garden must be prosecuted with all energy.

February is fast coming in, and in the kitchen garden Peas may be sown twice during the month, the first sowing being of early, and the next of second early sorts. The early wrinkled varieties are very superior in flavour, and may be used for the first and also for the second sowing; but it is well not to depend upon wrinkled Peas entirely for sowing at the early part of the season, as they are not so hardy in constitution as some of the commoner sorts. Make a good sowing of Early Longpod Beans to succeed the Early Masagan. The Savills Longpod is a Bean of exceptionally good quality, and ought to be grown by everyone. Sow in a frame a crop of Early Horn Carrot, and also sow Lettuce, Cabbage, and Cauliflower seed, and do not apply too much heat, but raise the plants in a moderate temperature, so that the various changes which they have to pass through may not interfere with their progress. Let the Cabbage beds be filled up where vacancies have occurred, and take the first chance to have the soil stirred among the plants. We have been in difficulties lately as to the working of the soil, and therefore much work will have to be done in a hurry, and many crops must necessarily be put in at a disadvantage.

Plant Potatoes in frames—the sets which were laid out last month to sprout, and take care that the next lot of sets to be planted are laid out carefully, so that they may not be injured in any way. I do not anticipate a very early season for outdoor Potatoes, as I think the soil is likely to be in a state adverse to their well-doing. I do not like to see the sets sprout too soon, for if in activity too long the tubers become partially exhausted, and a satisfactory crop cannot be expected from them.

Now is the time to plant the Jerusalem Artichoke in a soil that has been well turned up and a fair amount of manure incorporated with it. This is a very quick-growing plant, and therefore requires some stimulant in the soil to help it on; it then produces a profitable crop. The soil for Parsnips should also be prepared, for although this is a vegetable less thought of than some others, it is yet one of the most serviceable. If the seed is sown early it allows time for the roots to develop, and other crops more particular can be attended to as the time comes on. The Parsnip likes a deep and rather heavy soil; if given in a loose soil the roots are likely to be in a state adverse to their well-doing.

Prepare the soil for all other crops as the weather will allow, for time is advancing towards spring, when all must be busy.—
THOMAS RECORD.

DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

HARDY FRUIT GARDEN.

We seized the opportunity of two days' fine weather with frost to mulch all the fruit-tree borders. The manure was wheeled on to the ground and spread evenly over the surface. It will not be dug-in for some weeks yet. Raspberry bushes also receive a good dressing of rich manure after all the old stems and superfluous canes are cut away. It is not well to allow too many canes to remain on each stool, as they are not likely to bear such good fruit if the branchlets on which it is formed are too close together; four good canes are a sufficient number to remain on each stool. When they are trained together to one stake under this form of culture the plants ought to be 4 feet apart. We have before stated, however, that the best crops were obtained when the stools were about 2 feet apart and the canes trained to a stout wire about 3 feet from the ground.

The planting of all hardy fruits, ought to be finished as soon as possible. For Raspberries the ground ought to be well trenched and manured. The same may be said of Currants, intended for all small fruits. After planting the surface of the soil over the roots should be mulched with manure; this is of the very greatest advantage to all newly-planted bushes and trees, as it prevents them from suffering from the variable effects of our climate. We would also reiterate the remarks about care in planting. A hole ought to be made sufficiently large to allow of all the roots and fibres being spread fully out, and to give the trees or bushes a good start some turfy loam ought to be placed around the roots; this should be worked in amongst the fibres with the hand, then the ordinary soil should be placed over it, and the whole be trodden in with the feet—not very firmly, though, if the ground is wet.

Strawberry plants are sometimes put out at this season, but when they are planted so late this season is lost. Many gardeners take off their runners late in the autumn, say in October, and plant thickly on a sheltered border. These are the plants that would be planted-out in the quarters now. The soil must be pressed firmly about the roots, and the surface of the ground should be made neat with a digging-fork. The distance between each plant ought to be 2 feet. We can do nothing to our own Strawberry beds, but when the ground is sufficiently dry the surface will be stirred with a hoe, but only the surface, for to force the hoe into the ground even 2 inches causes great

destruction to the numberless fibres with which it is matted. For the sake of neatness as well as the health of the plants, all dead and decaying leaves should be promptly removed.

PINE HOUSES.

Since the beds were turned the bottom heat has increased to its maximum, but as the pots were not plunged very deeply into the bed the plants will not suffer from root-burning. We are now keeping-up the heat in the fruiting-house to a minimum of 70°, the temperature by day owing to so much sunless weather seldom rises more than 5° higher than this. We are glad of an hour or two of sunshine, which on one or two occasions has raised the thermometer up to 85°. The watchful cultivator will be on the alert at such times and will close the lights early in the afternoon. Bottled sunshine is better for the health of the plants than bushels of coke. The ventilators should be opened as early as it is possible to do so in the mornings; the least chink at the highest part of the house is sufficient, and this will insure a change of air for the plants in an hour or so. Those who are accustomed to work in houses with a high temperature feel the advantage of early air-giving on their own comfort, and the atmosphere that is most suitable for the health of man is, comparatively speaking, the best for plants. Succession houses where the plants have not yet started into growth have a lower temperature by 10° or 15°. If possible the suckers potted in August will be repotted in a few weeks into the fruiting pots; the bed will be turned and renewed, and a higher temperature maintained to start the plants into growth.

CUCUMBER AND MELON HOUSES.

For Cucumbers the temperature is kept the same as the fruiting Pine house. We are obtaining very fine fruit and sufficient for our wants from a few plants of Tender and True and a new sort sent by Mr. Kelway of Langport; it did well last winter, and has grown and fruited side by side with our own stock this season. It is much in the same way as Tender and True and quite equal to it. The variety has since been named Lord Beaconsfield. Kelway's Conqueror is also a fine-bearing useful variety. The young plants raised from seeds sown the last week in December are making healthy growth on a shelf near the glass. The plants have been potted singly into 60-sized pots: in a few days they will again be repotted.

Melons intended for the earliest crop ought to be as far advanced as the Cucumber plants, but we do not like to grow them in so high a temperature by 5°. The seeds vegetate best in a bottom heat of about 90°; but when the seed leaves have grown nearly to their full size it is as well to remove the plants close to the glass. Growth made at a considerable distance from the glass is not nearly so healthy even if the plants have the advantage of bottom heat. Melons do well in medium loam with a little leaf soil added, potting the plants moderately firm. After tasting many Melons purporting to be new sorts we go back to a good strain, Turner's Scarlet Gem, which is no Melon come true to its character. Its fault is that the fruit has a tendency to crack when at the point of ripening, but this is avoided by good management. Gilbert's Victory of Bath, or at least Gilbert's strain of it, is the best green flesh; it is early, free-bearing, and of the best flavour. Coleman's Easton Castle is a very fine flavoured green-fleshed variety and is highly recommended, but it has not been grown in our own garden. Those who prefer white-fleshed varieties will find one of the best in Colston Bassett Seeding.

PLANT STOVE AND ORCHID HOUSES.

Much of our time has been taken up in washing and cleaning the plants in order to free them from insect pests. If this is not done before the temperature is increased in the spring the pests multiply very rapidly. We make a point of having all insects destroyed in the winter months. This is the most difficult to eradicate if they become established in the house. Tobacco smoke applied at frequent intervals during the winter is the best way to destroy them, but then the utmost care is necessary if there are young fronds of tender Ferns or any young growths forming on choice Orchids. Some of the best Orchid-growers will not fumigate their plants at all, they will rather destroy the thrips by handwashing with scapy water.

Allamanda Schottii cannot yet be dispensed with; it is noble golden flowers are exceedingly effective. A plant of it is trained to the rafters of the stove. The growths have been closely cut back, and when the wounds healed the plant was well supplied with water. Specimen plants of Clerodendron Balfourii have also been well watered and the wood tied-in to the trellis; the leaves had not quite fallen from the plants. Dipladenia Brearleyana has been making a little growth through the winter, and with increased warmth and more water at the roots it will now grow vigorously. The growths are trained to the roof of the house to be tied to the trellis on a future occasion.

We shall take the first favourable opportunity to repot any plants requiring to be done. We have repeatedly urged the importance of doing this work well, and not delaying the operation until the plants have suffered injury from the roots being too closely matted together or from their being in a bad state from deficient drainage. When valuable plants are in question it is

worth while not only to do the work well but also to see that the right material is used. Many gardeners have not a command of acres of turfy loam to select from, and but few can procure suitable peat from their own estates. To grow hardwooded stove plants well turfy peat and loam are absolutely necessary; indeed, it is a question whether many species that have been grown in peat and loam would not be better if only turfy peat was used. Gardenias, *Ixoras*, *Dipladenias*, &c., do well in peat, and when this is of a tough fibrous nature and the pots are of a large size the plants will last in good condition for several years without re-potting. The turf should be cut about 2 inches deep, and after it has been stacked about six months it is ready for use. It ought to be torn in pieces by hand, and not chopped up, as is sometimes done. Those who go to the expense of purchasing plants will find it true economy to purchase suitable soil to grow them in.

Anthurium Scherzerianum is now a widely cultivated plant, and is one of the easiest to manage. It succeeds best in very fibrous peat. The pots should be filled to half of their depth with clean broken potsherds, a layer of clean sphagnum should be placed over the drainage, and some sphagnum and potsherds ought to be mixed with the peat used in potting. Plants which are in an unhealthy state must be examined, and if the soil has become sour from any cause it is better to remove the whole of it and to re-pot in the same or even smaller pots than the plants were in previously.

Orchids in many instances are starting into growth, but it does not follow that because they are making their growths that root-action has commenced. Any plants which have commenced making roots should be transferred to fresh material if this is necessary, but when the plants are doing well it is often the best policy to leave them alone. There is always more danger from over-potting than from under-potting. Those who have not the advantage of a show house for plants in flower will have to be careful not to saturate the atmosphere of the stove with moisture; a compromise must be made between growing plants and those in flower. Such fine Orchids as *Phalenopsis grandiflora* and *P. amabilis* are easily disfigured by the flowers becoming spotted from a damp atmosphere or water from the syringe.—J. DOUGLAS.

TRADE CATALOGUES RECEIVED.

- James Carter & Co., 237 and 238, High Holborn, London.—*Select List of Vegetable and Flower Seeds.*
 Wm. Paul & Son, Waltham Cross, London, N.—*Catalogue of Vegetable, Flower, and Agricultural Seeds.*
 William Bull, King's Road, Chelsea.—*Retail List of Select Flower, Vegetable, and Agricultural Seeds.*
 Felton & Sons, 56, Harborne Road, Birmingham.—*Seed Catalogue.*

 Dremmond Brothers, 52, George Street, Edinburgh.—*Catalogue of Roses, Liliiums, Gladioli, and Garden Seeds.*
 Charles Lee & Son, Royal Vineyard Nursery, Hammersmith.—*Catalogues of Roses, Fruit Trees, Ornamental Shrubs, Roots, Seeds, &c.*
 W. & T. Sampson & Co., The Nurseries, Kilmarnock.—*Spring Catalogue of Seeds, Plants, and Implements.*

TO CORRESPONDENTS.

- * * All correspondence should be directed either to "The Editor," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.
 Correspondents should not mix up in the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

BOOKS (*A Regular Reader*).—Our "Garden Manual" contains all that you want. You can have it post free if you enclose twenty postage stamps with your full address.

HYACINTHS IN POTS (*J. E.*).—The failure was probably occasioned by your having planted the bulbs too deep. They should have their necks just above the surface.

WAVERS (*Constant Reader*).—There are too many facts needed to be known to us before we could give an opinion.

ORNAMENTAL-FOLIAGE PLANTS (*X. Y. Z.*).—We should not consider *Araucaria excelsa* entitled to be exhibited among them; but some judges have admitted it.

CAMELLIA FLOWERS SPOTTED (*F. E.*).—It is the result of the cold and wet season. If the trees had been secured the discoloration would not have occurred.

RENDEL'S TANK SYSTEM (*J. C. B.*).—We do not know any maker of the apparatus; many houses are glazed without pntty.

SCIENCES AND ART DEPARTMENT (*J. N. Bateman*).—We cannot state our obtain the information you ask for.

CLIMBERG ROSES (*Lady T. and Others*).—We have forwarded your letters to "A PARSON'S GARDENER," who has informed us that he will reply to them next week.

CUCUMBER PLANTS (*A Constant Reader*).—We presume your frame has four lights—put out one plant in the centre of the bed under each light! Four plants will be ample.

VINE IN GREENHOUSE (*Idem*).—The Vine should not be started with additional fire heat. It will commence growing naturally in March or early in April, and will grow and ripen its fruit without other heat than that accorded the plants. To start the Vine early and grow it with much fire heat would ruin the plants. There is no necessity to cover the border with fermenting materials; a top-dressing of rich compost is all that is required.

TEN-WEEK STROUDS IN POTS (*Idem*).—It will not be wise to take the plants up from the open ground when advanced for flowering, but you may give them their blooming pots (having them well established in small pots) when you plant out your other plants in the open ground. The potted plants should be plunged in the ground or in ashes, watering occasionally with weak liquid manure.

PROPAGATING MAJORETTA-FERN (*E. S.*).—Instead of covering the frond with soil lay it upon the surface of the soil, and the spores will be shed and in time grow. The soil should be kept moist and shaded. The plant may also be increased by dividing it when potting in March.

CINERARIAS "BLIND" (*H. C. P.*).—We are unaware of any cause for *Cinerarias* coming "blind," and we think your plants will expand their flowers in due time provided the plants are healthy. *Cinerarias* often remain a considerable time in the bud state at this time of the year. Have patience, and we think that you will be eventually rewarded.

SUPPORTING HYACINTHS (*A. D.*).—Any florist could apply you with wire supports for Hyacinths in glasses. A wire may be bent so as to be attached outside the glass. If in pots the accompanying wooden shows a mode of support. The bulbs should be plunged in the borders after flowering and without injuring the roots, but they will not flower well next year.

INARCHING VINES (*A. B. P.*).—We fancy Gros Colman would not be a good stock to work upon. The best sort to work on it would be Black Hamburg. Work Royal Muscadine on Early Snyras. These (Black Hamburg and Royal Muscadine), are the best two Grapes for a cool greenhouse.

ROSES AND CAMELLIAS (*Hull*).—As your Rose bushes have been planted we advise you to mulch the surface of the ground with manure. Syringe the leaves frequently with clear water in dry weather, and keep free from insect pests. Frequent syringing is the only way to keep Roses in health. Any sorts of Camellias will stand the winter, but those varieties which open well under glass should not be planted-out, as the flowers of others will not open freely out of doors.

Fig. 12.

PEA FOR EXHIBITION (*A Young Gardener*).—Veitch's Perfection.

FLOWERS FOR BOUQUETS IN AUGUST (*Idem*).—*Staphanotis floribunda*, *Eucharis amabilis*, *Oxotylus crispus*, *Statice profusa*, *Dendrobium formosum*, and choice Roses in bud.

SIX ROSES FOR EXHIBITION (*Idem*).—Charles Lefebvre, La France, Marie Baumann, Princess Beatrice, Alfred Colomb, and Maréchal Niel.

HOUSE FOR VINES AND PEACHES (*A Lover of Fruit*).—A house 15 feet wide by 25 in length will produce one hundred bunches of Grapes. We prefer straight to curved rafters. Our Peach or Nectarine to square inches of surface is an average crop. Plant the trees in an inside border; but the borders ought to be both outside and inside.

FIS IN SPAN-ROOFED HOUSE (*W. R. A.*).—You will be the most successful if you plant the trees out. There will be a border 3 feet 3 inches wide on each side of the path, and if you form a border 1 foot below the ground line it will allow you to put in a foot of rubble, and to fill up with compost to the top of the front wall, 3 feet. Plant one row of Fig trees down the centre. You can plant five trees on each side—viz., three Brown Turkey, two Gros Verts, two Bourjois Gris, two White Mareilles, and one Singleton.

ZONAL PELARGONIUMS FOR EXHIBITION (*A Constant Reader*).—The finest specimens we ever saw exhibited were grown in the following manner:—The plants were planted out in the nursery in May or June, and in June and July plenty of spawn to form good specimens during summer and autumn. The plants were potted into 7-inch pots before they received any injury from frost; they were wintered in a light house, and re-potted into their blooming pots (6 inches in diameter) about March or April; growth then progressed rapidly, and as they grew the roots were tied into position, and when the pots were quite filled with roots diluted manure water was freely applied. They may be had in good order about the middle of June. As your show is in August, it would be necessary to pick off all flower trusses that appeared until the end of May or the first week in June.

HEATING LEAN-TO VINERY (*J. Chapman*).—Two small stoves would be better for your purpose than one large one, as the heat would then be more regularly distributed throughout the house. We cannot say whether burning paraffin in stoves without flues would be injurious to the tender young shoots of the Vines or not. We have seen such used in rooms, and have not felt any inconvenience from them. Try one stove first, and then add another if that is not sufficient. We would rather have a brick flue, as being more safe; but there is no reason why you should not try stoves. The Grapes would be ripe by the middle of July if the Vines are started at once.

VINES IN POTS (*T. Maybury*).—Surface-dress the pots with loam and decayed manure in equal parts, and when the roots work into the dressing water occasionally with weak guano water.

BLACK ON FERN (*J. P. P.*).—It is a parasitic fungus. Sponge the fronds with a mixture of soft soap and water.

NAMES OF PEACHES (*J. P.*).—Hubbard's Farmkin. (*Struan Robertson*).—Reinette Diel. (*Graetz*).—1, Court of Wick; 2, Ords; 3, Marzi. (*Col. Simpson*).—1, Cox's Orange Pippin; 2, We cannot identify. (*W. W.*).—Apple; 1, Winter Quoining; 2, Winter Greening; 3, Not known. Pear: 1, Leopold's Pear.

NAMES OF PLANTS (*O. O. S.*).—*Libonia floribunda*.

POULTRY, BEE, AND PIGEON CHRONICLE.

WOLVERHAMPTON SHOW OF POULTRY, &c.

The eleventh annual Exhibition was held in the Exchange Hall, Wolverhampton, on the 24th, 25th, and 26th ult. This year a number of commendable alterations have been made in the arrangements of the Show. Hitherto it has been held on Friday, Saturday, and Monday, thus causing the birds to be away from home on the Sunday, and objections were raised by a number of poultry fanciers to having the poultry exhibited in the same room with dogs, the noise and barking of which being very injurious to the birds, by keeping them in a state of continual excitement. It has been consequently, wisely we think, determined to hold a separate Show for dogs in May. The number of classes have been extended, and a fourth prize added to every poultry class. Classes for cage birds have also been added, and any number of pens at prohibitory prices were allowed to be sent in the same basket. The above alterations were made in the hope of inducing a larger number of entries, and we are pleased to record that so far they have been successful, the entries as compared with last year having increased something like 30 per cent. Of poultry there were 877 pens, of Pigeons 161, and Cage Birds 74, or a total of 1113, an increase of about three hundred. The room, however, was too small for an exhibition of such proportions, and consequently most of the pens had to be contracted in size, and many were in positions where they could not properly be inspected, otherwise the arrangements were all that could be desired, and the Committee assisted with praiseworthy zeal in penning and repacking the birds, which were all sent off during the Thursday night. Taken as a whole the Show was undoubtedly the best in all respects which has ever been held under the auspices of the Society.

Game headed the list, and as a whole they were of remarkable quality, the *crème de la crème* having put in an appearance. In old cocks all the prize birds were Brown Reds and carefully selected. The fourth-prize specimen however struck us as being a grand bird, but there must, we suppose, have been something in the handling of him which prevented his taking a higher position. We could imagine no other reason for it. Black Red cockerels were a large class, Mr. Matthews as usual taking first and second with stylish hard-feathered birds, which undoubtedly were the pick of the lot. Brown Red cockerels contained a few birds of great merit. Here again Mr. Matthews was first, closely pressed by a stylish cockerel of Mr. Martin's, the colour of which we preferred to the first, but he did not quite command the reach of his successful rival. In the Any other variety of cockerels the first, second, and third-prize birds were Duckwings, Mr. Matthews again occupying the pride of place with a bird beautiful in style, fine in feather, and capital colour. A good orange legged Pile was fourth. In Black or Brown Red hens all the winners were Brown Reds, and Duckwings won all the prizes in the Any other variety class, in both of which classes Mr. Matthews was again *facile princeps*. We, however, should have transposed the positions of the second and third prize birds.

Malays were a good class, but the clay-coloured hens seemed to take the preference over the dark Partridge. It struck us, however, that the Game cross was very apparent in several of the specimens.

Brahmas.—The competition was strong in all the classes, the cup for the Darks going to Mr. J. F. Smith for an old cock of extraordinary good colour, remarkable quality, and admirable condition. Second a bird of capital quality but not so heavily built. Old Dark hens mustered twenty-three pens, but many of them showed a brownness in colour which was not pleasing; but probably the thoroughly unfavorable season we have just passed through may have had much to do with this. The class generally, however, was a good one, though many being old birds were rather out of condition. Seventeen pens of Dark cockerels competed, the first and second prizes going to highly meritorious specimens. Dark pullets brought a strong competition, first being a grand bird, shown in admirable condition, her pencilling being of a character rarely excelled. Second was a bird of extraordinary character, and when we mention that independently of the four prize specimens the Judge deservedly awarded three very highly commended, an idea of the strong competition may be imagined. In Light Brahma cocks Mr. Horsfall scored another victory by taking the cup for the first with his old Bristol champion, but he was not in such good condition as usual and looking a little the worse for wear. Out of the nineteen pens in this class only eight were mentioned by the Judge. Light hens were of an even quality throughout rarely seen, and among the Light cockerels were some of the grandest young birds that have been shown this season. A few among the Light pullets were of very high merit, but the generality of them were wanting in condition.

Dorkings were about the smallest class in the Show, the cup

going to a pen of good-sized Darks. In the Any other variety class first, second, and fourth were good Whites, the first very pure in colour. Third were Rose-combed Cuckoos.

Cochins throughout were wonderfully good, and taking them all through we do not think we have seen a better lot this season, but they were situated in about the worst position in the Hall, in a bad light, and the pens too small for birds of such size, consequently detailed examination was scarcely possible. In the old Cinnamons, in Mr. Burrell's pair was his old champion cock, and we should have felt quite disposed to have put him again in the prize list. Notwithstanding his mealy wing and a tinge of white in the tail he is a grand bird, a wonderful Cochin. The second-prize pair did not match, the cock being a perfectly Dark Cinnamon. The third-prize pen on the contrary matched splendidly, were fine birds, and had our preference for second honours. We also preferred the fourth-prize Buff pullet to any in the class, for besides being equally good in other points she excelled her more fortunate competitors in her colour. We do not remember to have seen a better lot of Partridge Cochins, and both in these and the Buffs, so far as we could gather, with the exception of the above-mentioned little difference of opinion the awarding of the prizes seemed to have given general satisfaction. Some little disappointment, however, seemed to exist in regard to the judging of the Whites and the award of the cup to pen 384, it being alleged by some most competent critics that there were several better in the class, and in particular the highly commended pen 689 (Tomlinson). The principal objections to the cup cock seemed to be that, although he was a very large bird, he had too much daylight under him, was too hollow at the front, had considerably too much leg, and stood badly—was, in fact, inked. The second-prize pen we believe contained the cock which won first at Birmingham. As a lot, however, the class was the best we have seen for a long time.

Houdans.—Good classes, and in both old and young the hens and pullets were superior to the cocks. The first-prize chickens evidently won on account of their perfect comb and crest. It struck us that all the winners had the desired leaf comb. In other variety of French fowls first were Orives and second La Flèche. A good class, and as in the Houdans the hens and pullets comprised the better part of the pens.

Spanish.—Noted as the Wolverhampton Shows have always been for the quality of their Spanish classes, they were, we think, surpassed this year. There were only two classes, one for cocks the other for hens irrespective of age, and the general merit throughout was such that we cannot enlarge it too highly. An additional cup given by the Committee was awarded to an old cock, and in this class, in addition to the four prizes, four very highly commended and five highly commended were also added. In regard to the hens the Judges expressed an opinion that they never saw so keen a competition generally throughout a class as took place here. First was a grand bird in exquisite feather and condition, and we believe ran the cup cock close for the extra award.

Polands were divided into two classes, "White-crested Blacks," and "Any other variety." The cup for Polands, French, and Spanish for some reason going to the Black Polands. In the "Any other variety" a good pair of Silvers belonging to the Countess of Dartmouth were first, closely pressed by Mr. Beldon's Dorchester cup pen, the effects of the recent journey of which evidently told against them in the competition. Third were good Golden, while Mr. Adkins on this occasion had to content himself with a fourth, but it is impossible both to sell one's cake and eat it.

Hamburghs were very good classes especially the Golden-spangles, and it must have been a difficult task for the Judge to select the winners, so many being good. First and cup fell to Mr. Dean of Keighley, Yorks, with a very fine pen indeed. In Silver-spangles Mr. Beldon won with a pair, the cock in which is the most perfect in handling we remember to have seen. He is in this respect something to remember. The first-prize pen of Golden-pencilled contained an old cock which we remember in the same position at Birmingham matched with a very good pullet. Silver-pencilled were a small class, but the winners very good.

The Variety class was a large and excellent one, first being good Black Hamburghs, second Cuckoo Cochins, third White Leghorns, and fourth Bearded Sultans. There were Selling classes, one for Brahmas, Dorkings, and Cochin cocks, which comprised seventy-eight entries, first and third being Buff Cochins, and second a Partridge Cochin. A class for pairs of hens same variety, and two classes for any variety except the above, one for cocks and the other for hens, the prices in all not to exceed 50s. They comprised many good birds, which no doubt soon found purchasers.

Ducks.—The Aylesburys were few in number, but the winners of high quality. The Ronens were also excellent, and in particular the second-prize drake, but many were not over their match. The very pen brought in the Any other variety class received favourable notice from the Judge, the whole being of an

ing from the advantages accruing from the cultivation of the smaller varieties, it is to the larger that we must look to advance the breeding of Rabbits and to educate popular feeling in their favour. Classes for Belgian Hares are, however, being provided at our principal Rabbit Shows—as for instance, the Manchester Show of the New National Society of Rabbit fanciers, the late Crystal Palace Show, and several of the larger county shows, so that in a few years the position of this variety may be confidently expected to improve. It certainly should do, as it has many claims upon our good opinion, not the least of which are its great value as a flesh-producer and the ease with which it can be reared. Among the minor uses of which it may be made we may mention its extreme value as a parent. The difference in size and appearance can hardly be imagined when a prick-eared doe is paired to a buck of the breed instead of to one of its own size. The difference in the cost of keep is practically nil, and the primary outlay but a few shillings, while the success of the venture will surprise the most sanguine speculator. As the last point in its value may be mentioned its extreme usefulness for turning down in warrens. The breed being very hardy can easily find its own living and is very useful in improving the stock of the ordinary warren. Rabbits of both sexes turned into a warren will soon produce appreciable results.—G.R.A.

PROGRESS OF APIARIAN KNOWLEDGE.—No. 2.

In my former communication on this subject I began with the history of the queen bee, and pointed out that in one or two points—notably in the case of the wonderful discovery of Von Siebold—apiarian knowledge had made considerable strides since the days of Huber. In his discovery of the virgin birth of drones we have a most surprising fact in nature, and one which adds greatly to the dignity and interest of the study of bees. Practically, so far as we know, no great result of benefit to the profitable management of bees has come out of it, because I think it is not yet ascertained that these virgin-born drones have the power of propagating the species. Presumably they have, otherwise it is difficult to see the use of this extraordinary power of developing male life, seeing that usually drones are in excess in most hives. A most interesting point would be the discovery that worn-out queens retain the power of producing drones at the close of their existence—as the last vital act of nature after they have ceased to be capable of producing workers, for this would show that *parthenogenesis* in their case was a special provision for maintaining the royal succession, even at the ordinary periods of the year when drones are ordinarily absent from the hive. Let science again direct our experiments to the elucidation of this question. If our friend Mr. Woodbury were alive his patient perseverance would soon find the answer.

Another point connected with the queen bee in which we have gained a step in knowledge, is the ascertained fact that queens are not always animated with that intense jealousy and hatred of one another which Huber had observed; indeed, it seems as if such jealousy might prove the exception rather than the rule. In several instances reported in this Journal two queens have been observed living amicably together in the same hive, performing the functions of their condition side by side without molestation either from the bees or from one another. There is no doubt, however, that one queen in a hive is the ordinary rule, save at swarming time, when very often two or more young queens will be found for some days roaming about the combs without let or hindrance. After a time they disappear, numbers being destroyed in the act of swarming. These are probably in most instances despatched by the bees themselves, and not so commonly, as is supposed, by the queens attacking one another. The ordinary method by which the common bees destroy unnecessary queens is by suffocation and starvation in the form now termed "queen encasement"—a method of regicide which was frequently noticed and observed by Huber; but he is certainly mistaken when he says that bees never sting the queen to death. The great jealousy of the queen seems to be excited, as he constantly noticed, by the presence of young queens in the pupa state when swarming is at hand. If present, the mother queen will eagerly attack the royal cells, tear a hole in each sufficient to admit of her abdomen being introduced, and sting the more or less developed occupant to death.

Again, Huber tells us that he never could introduce a new queen successfully into a hive till after the lapse of twenty-four hours or more after the removal of the old queen. I generally find a quarter of that time sufficient for the purpose, provided the bees have really become generally aware of their loss. It is essential that they should feel thoroughly distressed, and should have been for some hours in despair, before they will hail with pleasure the presence of a new queen. Nor is it then safe to introduce a stranger queen without using much precaution, because some bees discover their loss less rapidly than others. The fact, however, is beyond doubt that bees will wel-

come a new queen very much earlier than is generally believed. I have proved it many times, even so lately as last autumn, as has been recently recorded in the pages of this Journal.

It is still believed that queen bees never leave the hive save at swarming time for any purpose save to mate with the drone in the open air. I have no evidence to produce to the contrary. As, however, I am inclined to believe they do occasionally quit the hive at other times, it is a question whether they mate with the drone more than once in their lives. My attention has been directed to several instances where hives have unaccountably lost their queens in the full vigour of life—cases where they have been seen walking about the entrance, and where they have been found in the perilous bond of queen encasement suspiciously near the entrance just within the doorway. But evidence is not sufficient to authorise assertion of the fact. It would be very desirable if special attention could be directed to this question by our numerous apiarian friends.

I believe I have gone through all matters connected with the queen bee in which there is reason to think that our knowledge betters Huber's instruction. If any of your readers can correct or supplement what I have written it is open to them to do so.—B. & W.

MOVEABLE VERSUS FIXED COMBS.

Your old and excellent correspondent, Mr. J. Lowe, in connection with the above discussion, contributed an article entitled "The Battle of the Hives," wherein he rakes together some of the ashes of a controversy he and I engaged in four years ago; and from the little support afforded by the fraternity to the latitudinarian views he then promulgated I thought he had seen something of the untenableness of his position, but the old adage is often verified—

"A man convinced against his will
Is of the same opinion still."

From his theoretic eminence Mr. Lowe's eye sweeps over the distant American continent and scans our nearer home fields, and the din of "The Battle of the Hives" so rates upon his ear, that at the mention of the simple question—"Which is the best hive?" sounds to him a very foolish one, and causes him to add, "Certainly I could not with all my experience presume to answer it;" to which I can only reply, How consummate, then, must be the folly, how limited the experience of those bodies of apiarians banded together in the south as the "British Bee-keepers' Association," and in the north as the "Caledonian Apiarian Society," with all their writer branches, when they actually give so liberally out of their means the much-coveted prize, and decorate with their medals Mr. Lowe's myth "the best hive" in all their sections? Is not the prize list of every apiarian society in Europe and America a protest against your correspondent's hypothesis?

The recent discussion originated in a comparison of harvest results obtained not from *all* but simply the Stewarton hive, and moveable combs and system of management usually followed with it on the one side, and the large straw hive with fixed combs as championed by your correspondent Mr. Pettigrew on the other. So far as Mr. Lowe can venture from his equality stronghold, he rather lends his influence towards fixity and the straw skeps; but I am afraid Mr. Pettigrew will look rather askance at his sceptical ally, for does not he (Mr. Lowe) proclaim "That no such adventitious circumstances as the kind of hive can have much of any influence on the amount of stores collected by the bees," and is not Mr. Pettigrew justly proud of the large harvests reaped by his improved hives?

From your correspondent's standpoint we will all very readily admit that the hive cannot of itself make nor reap, nor even store honey, no more than the pen in my hand can of itself write these lines: they are both pieces of inanimate matter. It is puerile to state this, but so far as we can comprehend it is the gist of Mr. Lowe's contention, a mere playing upon words, which we fail to see can in any way further the cause of apiculture we have all so much at heart. The hive must be peopled, the reapers have their implements, even the store its porters, the writer his pen, and then what follows? In exact proportion as they are severally efficient will be the quantity and quality of the work produced. Mr. Lowe may deny this;—but if we can only say it may amuse the theorist to throw up its glittering soap bubbles, it only damps the practical hand to crush them.

With reference to my competitive hives, the Stewarton and straw, a correspondent, "W. J. C." says, "The Stewarton was doubt was crammed completely, although we are not told so," to which I reply, that it as well as the straw were "crammed," but only with the progeny of their respective queens, and neither had any extraneous aid whatever saving what was narrated. With regard to the same hive Mr. Lowe says, "There is some ground for suspecting that it was not right with that [straw] colony," but I can assure him it was in every way in perfect health and condition; and further, that "the same results might occur even if the competing hives were both Stewartons," this

I deny. And then follows, if "A RENFREWESHIRE BEE-KEEPER" thinks the reverse he will kindly state how the results are to be otherwise accounted for. Is it by reason of the form, material, or construction of the Stewarton hive which enabled it to eclipse so greatly the straw skep in smothering stores? And I answer in the affirmative, holding that if both your correspondents were more practical spairiuses they might have seen it for themselves. First, "form," the straw hive being the usual dome shape, prevented any super sitting conveniently on it, saving the Abingdon glass, and even to get it placed I had to cut out a portion of the apex with my penknife, and lashed the glass with cord to the protruding cross sticks. Then the material of the super portion of that hive being glass told much against the return, the additional labour to get the combs built and attached with extra expenditure of honey to keep up the temperature continuously therein while storing and sealing went on. I have heard it estimated by experienced bee-keepers in glass-filling that their bees would readily store from 3 to 4 lbs. honey in wood for every one in glass, and to crown all, the extra breeding and supering area in the Stewarton over the straw must alike have stimulated the fertility of the queen and the acquisitive principle, in the ever-increasing band of her more numerous staff of honey-gatherers.

In opposition to your correspondent, Mr. Lowe's theory, "That no such adventitious circumstances as the kind of hive can have much or any influence on the amount of stores collected by the bees," I can give a striking and conclusive illustration. There stands in my apiary for the last ten or twelve years, including the magnificent seasons of 1868 and 1876, a by no means small hive, with usually one of my most prolific queens at its head, a non-warmer in perfect health, a foul cell never having been seen within it; and yet, while those "best hives," my marvellous Stewarton reapers, were throwing off in those good years in their nine and ten supers a piece, if since its establishment has not yielded up a ounce of honey; on the contrary, each autumn had to be liberally fed. And how can you account for the astonishing difference? as to the perplexed reader. We will allow Mr. Lowe to do so. By reason of the form, material, and construction, the defaulter being the observatory stock of—A RENFREWESHIRE BEE-KEEPER.

OUR LETTER BOX.

EGG WITHIN AN EGG (J. G. S.).—We have seen a perfect egg within another perfect egg, but it is very unusual.

LEGIONS AND DOMINIONS (A. H.).—They have been advertised. You may refer to the advertisements in our columns.

NUMBER OF HENS (C. S.).—Twelve hens are too many for one cock if the eggs are to be raised. Six or eight will be enough, but you may try eight. The number of hens that may run with a cock is a question of temperature. We know from experience that in December you cannot depend on the eggs of four hens running with a cock, however young and healthy. At the end of January you may put six hens safely, at the end of February eight, at the end of March ten; after that you may, if necessary, put twelve, or even eighteen.

GREENHOUSE FLOOR FOR CHICKENS (Idem).—The floor of a greenhouse is always suggestive to us of damp bricks. Nothing can be worse for chickens. If you mean to keep them there, cover the floor with very dry road grit. We do not like the atmosphere of a greenhouse. We have now strong-growing chickens. We keep them in an old disused barn with the old earthen floor. They are supplied with dry grit and with growing grass. They have no artificial heat, and have only beer to drink. We always find January chickens the easiest to rear.

ROUEN DUCKS (F. G. S. R.).—There is nothing to be said about Rouen Ducks beyond that which was known many years before the present breeders took one or were known. It is a matter of fact that they should be counterparts of the Mallard and Wild Duck. The difficulties of judging in those days were the bills of the Ducks and the rick of the drakes. Then there came the white flight. This gave trouble for a time, but it was disposed of. It is useless to state the fact that wild birds are the models on which to judge the Rouen. Twenty years ago there were people who sold their leaden-coloured bills as admissible, just as you do for "dark stems." The opinion now quoted is not good for much. Chain armour belongs to the Gadwall, not to the Rouen. The "curtlet" feathers have nothing to do with the question. The Rouen is principally a bird of size and weight—it is a bird of food. Formerly it was Sibb. below the Aylesbury, now it is above it in weight. It may suit those who have small birds to save themselves behind feather, and those who have large birds to depend on size. We blame neither, we have no right to do so; but we believe in Nature, and we should be anxious to know who set forth that Rouen Ducks or drakes should have dark feathers. Looking at the two we have no hesitation in preferring the light feathers. We cannot agree with those who would make food birds birds of plumage; and we can only add the birds for exhibition, as belonging to the food of a country, are not only added if they have no glaring defect according to the weight they bring to the common scale, but to the particular shade of three or four feathers. This was and should be the aim of poultry shows.

BELGIAN HARE RABBITS—"I wish 'GETA' (p. 73) would give us the ground on which he contradicts the assertion which is now generally accepted—namely, that the Belgian Hare Rabbit is a cross. That cross-bred is a title in a general fact, but the case of these Hare Rabbits has found its way into scientific books and into the popular conception. I was, therefore, surprised to see it so flatly contradicted.—G. S.

THE GROWTH OF CANARY'S BILL (Amer).—All birds in confinement are subject to an overgrowth of the beaks and claws, and it is necessary that Canaries and other small cage birds, in particular be provided with grit sand on the cage bottom, and likewise a piece of mortar to peck at, placed betwix the wires. The mortar or a piece of cuttle-fish hung inside the cage will

engage the attention of the birds' beaks, and in a great measure keep down the horny growth of the beaks. Cuttle-fish may be obtained from the London or other bird dealers. The most effectual remedy it to pare the beak with a sharp pen-knife, or with the claws with either a knife or pair of scissors, but not with a file. The end of the red ray or vein in both beaks and claws, when held against a strong light, will show exactly how far the operations may be performed. Aged birds are more liable to an over-growth of the beaks and claws than young birds, but even two-year-old birds require their claws trimmed, which enables them to obtain a better grasp of the perches. Many valuable cage songsters have been lost through being found head downwards, trapped in either the wires or perches with their sickle-shaped claws.

AVIARY IN CONSERVATORY (F. P.).—You may with a fair amount of success be able to keep about fifteen or, at the most, a score of small birds, in the aviary which you give us the dimensions of. Canaries will live in harmony with such birds as Goldfinches, Brown Chats, Siskins, and Redpolls, for each being granivorous in their habits will fare well with the same diet. A mixture of hemp, millet, canary, rape, and fax will suffice for their rations. On the bottom of the aviary let there be a plentiful supply of rough sand, and if the birds have access to a bath they will keep their feathers in good order. Two or three Mule birds would add to the variety in the above-named lot, and variety is worth a consideration. If you can avoid it, do not let the perches directly cross over each other, or those beneath will become soiled. For an aviary, we think if the perches be fixed in a semi-transverse direction a most objectionable arrangement will be avoided.

HIVES OF BEES BY RAILWAY (J. H. Howard).—The loss by breaking down of the combs must be borne by you. You directed how the hives were to be sent, and refused to let the vendor pack them as he wished.

REMARKS.

- 24th.—Rain in the night and early morning, but fine by 8 A.M.; the day throughout bright and pleasant. Lunar halo.
 - 25th.—Rain in the night and early morning, but fine by 11 A.M.; the day throughout bright and pleasant.
 - 26th.—White frost in morning; very fine all day and night. Lunar halo.
 - 27th.—Rainy day and night.
 - 28th.—Damp, but not rainy morning, rain in middle of the day; but fine afternoon and evening.
 - 29th.—Fair, but very bright at noon; rain in afternoon, and very high wind in the night.
 - 30th.—Wind very high, with sudden heavy showers, with bright sun at intervals all the day; very heavy hail shower at 10 A.M.
- Rain of temperature greater each last week, and weather variable. Hot sun on 24th and 30th.—G. J. SIMONS.

COVENT GARDEN MARKET.—JANUARY 31.

Good samples of late Grapes are now becoming scarce, and consequently realising good prices. The Apple market remains the same, with business very quiet.

From observations taken near London during forty-three years, the average day temperature of the week is 44.5°; and its night temperature 30.3°.

GLAZING WITHOUT PUTTY.

OBSERVING that inquiries have been made on this subject I submit my experience. I do not approve of glazing sashes entirely without putty, but I am firmly of opinion that "top putty" is worse than useless. Many years ago when the roofs of the houses under my charge were undergoing the usual routine of repainting, &c., it occurred to me to have the putty entirely removed from one length of lights—painting the sashes without it, the remaining portion of the house being repainted, painting, of course, over the putty after it was set. The lights which have not been puttied for nearly twenty years are now in better condition, and there has been less leakage from them than the others which have been periodically repaired in the orthodox manner of patching the putty and painting over it. Unless very special care is taken the top putty on the roof of a vinery or forcing house will shrink and in places become separated from the wood. The crevices between the glass and the putty, and the putty and the wood, may be so minute as scarcely to be noticeable, yet they are sufficient to admit the water; and when once the water penetrates beneath and behind the putty it cannot easily evaporate and the wood is almost continually wet, accelerating its decay, and the putty is also prematurely peeling off, rendering further, and as I believe unnecessary, outlay incumbent in paying for time and material in repairs and making the roof watertight. I believe, therefore, that "top putty" is injurious, but I think bottom putty valuable.

Acting on my direct experience and on much observations in different places, and supported by the advice of a very practical joiner and glazier, the last house erected under my charge was glazed as it was termed "without putty," but in reality without "top" putty only, the glass being firmly bedded in putty—thus putty was used beneath the glass, but not above it. Special care was employed in placing the putty in the rebates of the sashes, using it good, plenty of it, and placing it in regular layers—the last condition being very important. The wood previous to applying the putty was well painted twice. The glass was firmly—very firmly—pressed down into its bed of putty, each square being secured in its place by driving two small copper tacks into the sash-bars at the lower corners of each square; the "lap" of the next square above, of course, keeping that portion secure. When the glazing was completed three good coverings of paint were given the upper portion of the sashes, painting also about an eighth of an inch on the glass. When completed the first shower of rain was anxiously waited for. In due time the shower came—a "regular rainy day"—and although the roof was rather flat not one drop of rain came through it. Further, during the deluge which has been lately experienced the roof has proved to be perfectly "watertight," while in other houses glazed with top putty the water found its way through in an unpleasant manner. I am quite cer-

tain that the roof of a glass structure having no putty on the outside can be kept in good condition with less cost than can one where the top putty is used in glazing; therefore by the non-use of the outside putty two savings are effected—first, cost in the saving of material, and after-cost in keeping in order in saving both material and labour. But while I consider top putty worse than useless I lay special stress on the importance of good bottom putty (and good workmanship) for embedding the glass. There may be others who do not see the value of putty at all, and they may have good reasons for abolishing it; but I can only record my actual experience.

All sashes, for anything I know to the contrary, may be glazed as I have suggested—I mean sashbars do not need to be made specially for the carrying-out of the plan. It is true that when top putty is not used the rebates of the sashbars do not need to be so deep, but that is a point of no real importance. I am not aware that my experimental lights from which the putty had been removed were ever observed by any visitor, so that their appearance was not in any way singular. The glass is quite as firm without top putty as with it, the roof is more efficient, and the appearance is as good. When the squares of glass are at all large—say 20 inches by 12—glazing is much more quickly done without top putty than with it; but with small squares and closely arranged sashbars outside, putty cannot perhaps be so advantageously abolished.

As the result of my experience my plan for the future will be (until a better mode is pointed out) to abolish the use of outside putty entirely, but to use good bottom putty liberally and well in the glazing of glass structures.—STEWART AND GARDENER.

THE CULTIVATION OF THE RASPBERRY.

"PRACTITIONER" on page 67 has alluded to the cultivation of the useful and popular fruit, confining his remarks to canes trained to stakes or trellises. I wish to remind all whom it may concern that Raspberries may be grown successfully without being trained at all. In the fruit fields of Kent, and also in other parts of the country, many acres of land are devoted to Raspberry cultivation, and excellent crops of fruit are obtained from canes which neither have nor require any stakes or wires to support them.

When grown largely in open fields the canes are planted thinly—that is, the rows are nearer 4 than 3 feet apart, the "stools" in the rows being 18 inches distant from each other. The canes are planted singly, and are mostly kept singly, though occasionally two and now and then three are allowed to grow from each stool, provided they are of a short-jointed character. The principal point aimed at is the securing of stout short-jointed canes. These are essentially fruitful, and are sufficiently strong to be "self-supporting;" hence the adoption of the practice of planting thinly and preventing after-crowding. The canes thus thinly planted in an unshaded place seldom grow tall; they are pruned during the winter,

each being left at the height of 3 feet. With an otherwise judicious system of culture, as manuring and cleanliness of the ground from weeds and suckers, valuable "hedges" of fruit are produced sufficiently rigid in themselves so as to be secure from injury by boisterous weather, and the fruit can be conveniently and expeditiously gathered. Raspberries thus cultivated yield (taking one year with another) highly profitable crops, and the plan is worthy of adoption in the vicinity of large towns, where the demand for this favourite fruit is frequently greater than the supply.

Raspberries also grow as well, if not better, than any other fruit under the shade of trees. The home of the Raspberry is in the woods, and this fact conveys a hint that it may be profitably turned to account as an undergrowth crop. In many fruit orchards it is thus turned to account in a profitable manner. When this mode of culture is adopted it is found of special importance to plant thinly—that is, the canes should be grown singly, each having 3 or 4 feet of ground area. When the ground is kept clean and suckers are prevented growing, valuable crops of Raspberries are produced in orchards where the large trees are not closely planted and the shade is not exceptionally dense. It is not uncommon for Raspberries thus grown to produce crops when those in the open do not do so. Late spring frosts are frequently inimical to the Raspberry crops, and I have more than once known "wild Rasp" in woods plentiful when the canes in the garden have been barren. The woods afforded shelter from spring frosts, and similarly the shelter produced by orchard fruit trees has insured fruit on the "undergrowth" crop—the Raspberries. When the soil is heavy the leaves of the trees and canes afford almost or quite sufficient nourishment for the Raspberries, but a dressing of salt and soot, or guano, applied during showery weather in the spring is a profitable investment. When Raspberries are grown in the manner described they do not injure the fruit trees. I am intimately acquainted with an orchard having an undergrowth of Raspberries, and the trees in that orchard of Apples, Plums, and Pears, have for a period of twenty years produced crops of fruit fully equal to any in the neighbourhood where Raspberries have not been grown beneath the trees. The undergrowth crops in the orchard alluded to have been of substantial value to the owner.

Raspberries may also be grown in gardens on the same self-supporting principle. I have had excellent crops without the aid of either stakes or wire, and without bending the canes into a series of arches, and while the rows in summer have been attractive by their productiveness, in the winter they have never been considered unsightly. When wires and stakes are procurable it is right that they should be used in gardens, but I would not have anyone deterred from growing Raspberries on account of the absence of these extraneous supports.

I have grown Fastolf, Red Antwerp, Northumberland Fillbasket, and Carter's Prolific, and I give the preference to the latter for growing on the free-and-easy system alluded to. It is short and robust in growth, productive, and the fruit is large and of excellent quality. For growing on tall trellises Northumberland Fillbasket is suitable; it is very vigorous and produces fine fruit. Can any growers detail their experience with McLaren's Prolific?

Canes grow well when planted in February, provided the roots are not permitted to become dry during removal and transit.—A MARKET GARDENER.

POTATO PLANTING.

I QUITE agree with "A NORTHERN GARDENER'S" advice as to preparing seed Potatoes before planting, as on that, in my opinion, rests the foundation of the crop; and, like your correspondent, I cannot advise planting so early as January.

I have had fourteen years' experience in Potato-growing on two kinds of soil—the one a heavy black soil, such as the Briar delights in; and the other a light red soil that you can work at any time. I have tried the early planting recommended by "A YOUNG AMATEUR," and have been rewarded with a half crop of the worst Potatoes I ever grew. Many of the sets remained in the same condition as when planted, only the robust sprouts had disappeared and were replaced by a few wiry sprouts which had not the strength to push through the soil. So much for early planting.

During late years I have not planted a Potato on the heavy soil until April (after the ground has been dug and manured in the autumn), when the soil was dry on the surface, then forking it over, planting as the ground was dug, in rows not less

than 2 feet 6 inches apart, being careful not to plant too deep, say 2 inches, sowing a little gas lime mixed with ashes on the sets, and covering them with the next spit, always avoiding treading on the ground except when it has been dry. After this treatment I have had a full crop of sound Potatoes. On the red land I follow the same plan, only planting deeper, and the rows a trifle nearer except for large-growing sorts.

I have used gas lime mixed with ashes, and find it a good remedy against insects.—J. H. DIXON.

THE ROYAL HORTICULTURAL SOCIETY.

KNOWING nothing about the Society, its position and perplexities, beyond what I have endeavoured to learn from reading the papers, it has occurred to me that I may venture to say something which cannot well share a worse fate than much that has been written by those who are exposed to be well acquainted with the subject in all its intricacies. In the institution with which I am connected all the principal gardening papers are taken, and opportunity is also afforded the members for reading the daily press. It is from this source, therefore, that I have derived my information, and I have read the several reports and letters which have appeared by the light of such common sense as I happen to be endowed with. As to the parties individually concerned in the Royal Horticultural Society I know nothing, and it is consequently not possible that I should have any special sympathy for the "Kensingtonians" and their friends—people whom I have never seen, and in all probability never shall see. I am neither disappointed in anything that has occurred during the past nor prejudiced in regard to any contingency of the future, and possibly on that account I can regard matters the more calmly than at least some can who have written on the subject, and who are to a certain extent identified with some particular "policy" that has from time to time been mooted. I am not committed to any "plan," and no man or "party" has any claim to my support. In a word I am independent, and will look at the position from that standpoint. I am a gardener earnestly desirous of seeing horticulture flourish and the Royal Horticultural Society healthy and prosperous. That is my desire, as it is that of hundreds of others in a similar position with myself.

In reference to the Society, if one thing more than another has been impressed on my mind it is that the present Council are earnest in their desire to promote the art which the Society they represent was established to foster. I have gathered this from the writings of many men, and from, I think, every section of the gardening press—that the Council is composed of earnest practical men, whose one great object is to promote horticulture and render the Society, in fact as well as in name, a real horticultural Society. That appears to have been generally admitted, and the shows and meetings, as reported, have been much more successful since the present men were at the head of affairs than before they were appointed to their honourable yet onerous office. The work done at Chiswick has also been eminently useful and instructive.

If I appreciate the position rightly, I am also under the impression that the Council were not only willing but anxious to disassociate the Society from the "fashionable lounge" at South Kensington, so that they might be at liberty to better carry out purely horticultural work. If I am correct in my recollection they made proposals to and obtained a hearing from the Royal Commissioners towards the carrying-out of this object—an object which would have been effected but for the decision of the debenture-holders. I do not blame this important body for defending their own interests, but simply record the fact as one which cannot be overlooked in considering the present position of the Society. As I understand the matter, the action of the debenture-holders placed the Council in this position—that be they ever so earnest in their desire to out themselves (the Society) adrift from South Kensington, they are absolutely powerless to do so for a period of at least two years. That I conceive is an important fact to be remembered. Let us, then, admit that the debenture-holders and the Court of Chancery compel the Council to retain the gardens at South Kensington for a certain period, and what next?

Two courses are now open for adoption: first, the practical closing of the gardens—letting them go to ruin—and ostracising the local residents; rejecting the support which many have given, and it is presumed many are willing to give again; powerfully aiding to place the Society in a solvent state, enabling it as far as possible to prosecute its legitimate functions.

That is one course. The next is to close the gardens and leave "bag and baggage;" disregarding the local Fellows, rejecting their aid, and depending on the purely (the country) horticulturalists for support. That policy has a fine, a plausible, a patriotic sound with it, but if examined closely is it not a deceptive sound? It has been announced that a large number of horticulturalists are ready to come forward, but mark the conditions—provided the Society leaves Kensington. Now, as it appears to me, comes the vital point. The Council cannot by the action of the debenture-holders relinquish the South Kensington connection, and because they cannot do what is impossible horticulturalists, as a national body, refuse their support. That is one dilemma. The other is this—that the gardens are an integral part of the Society for say two years; the country horticulturalists refuse to give adequate support, and, as it seems, to prevent the Society lapsing into bankruptcy—instead of closing the gardens and rejecting the only means of existence for the time being—the Council prefer to make the gardens in some degree attractive and command that support which can alone preserve the Society in a solvent state, preserving it until better days dawn and until it can depart in peace to perform the real work which both the Council and horticulturalists so earnestly desire.

Because the Council have so determined—averting bankruptcy and saving the Society—a furious howl is raised, vapouring fulminations are launched by disappointed men, and feeble arguments are advanced in favour of the "perish-the-Society" policy, and the Council are pronounced as traitors by those who know not what they say. The charge is ridiculous. Every member of the Council is a stranger to me, but my common sense tells me that they are gentlemen of honour and character or they never would have been appointed. But why not let the Society merge into bankruptcy and then start afresh? some may ask. It is very easy for the "askers," but how about the Council? In case of a breakdown would not all the odium rest on the members of the Council? and would not those who write screaming letters to the papers about the dignity of horticulture be the first to point the finger of scorn at them?

I have never written a line about the Society before, and should not have done so now had I not read in a Saturday's paper a wild tirade from a gardener whose reckless statements are a libel on the common sense of the craft to which he belongs. That writer shall not, at any rate without one protest, assume to represent a body who can work as well and think as clearly if they cannot talk and write as glibly as he can. A paragraph has lately been going the rounds of the papers describing an extraordinary phenomenon of a sea serpent wrapping its coils round a whale and dragging it into the mud. I was forcibly reminded of that ludicrous circumstance on reading the burst bubble on Saturday last, and to which the Editors from a sense of self-respect felt bound in a great measure to refuse their sanction.

The right—the seemly—way as it appears to me, is to wait and give the Council a hearing, and then, and not till then, to pronounce a verdict on the evidence then adduced. One-sided judgment is unfair, unmanly, and unjust.—A NORTHERN GARDENER.

OLD-FASHIONED ROSES.

WHEN I wrote the article on climbing Roses which appeared on page 41 I had not the remotest idea that the old Roses therein mentioned could have commanded the attention which has been evoked respecting them.

Letters have been sent to me (through the Editors) from various parts of the country—aristocratic letters, clerical letters, and letters from villa residents, and even from artisans. I should like to give extracts from some of these letters, but fear they would occupy too much space, and besides the testimony they contain is not really required, seeing that the value of the old Roses named has not been controverted save by one writer, and him a "Saveg" whom I can deal with without supporting aid.

The purport of the letters was a desire to know where the old climbers could be obtained, or if cuttings of my proclivous Roses could be sold or given. Had I received but one or two letters I might have replied to them privately, but under the present circumstances I can only treat all alike by here saying that, after having well considered the subject, I do not feel warranted in asking permission to post cuttings of Roses (which are not my property) to different parts of the country.

I fear that that reply may be disappointing to some, but there is no reason that it should be so.

In the first place, I should not be (in the end) doing a kindness to the applicants by sending them cuttings, because at this season of the year Rose cuttings will not grow; and in the next place, to wait until they would grow would be a sacrifice of valuable time before their self-raised Roses were in a strong flowering state. Rose cuttings I find grow well when inserted in a shaded border during August or early in September, but are some time before they are large enough to cover a trellis or bower. Were I requiring a plant or plants of any of the old-fashioned climbers I should purchase them at the nearest nursery. Strong flowering plants may be purchased for 1s. 6d. each much superior to those ordinarily raised from cuttings in a private way. If my correspondents will adopt that plan I am certain that they will be much better satisfied than if I sent them cuttings which would probably die. Almost every Rose-growing nurseryman can supply all the sorts of "old-fashioned climbing Roses."

And now to the Rev. Savage, for he tells us that he is a parson. He submits a list of climbers for a church without attaching any conditions. The climbers named as being suitable (and I grant beautiful) for his territory are of no use whatever for hundreds of gardens where the Journal reaches. The Roses which I named will grow anywhere and produce such a bountiful profusion of blooms as to make "Cloth of Gold" ashamed of itself. The Roses of "WILD SAVAGE" will only grow in favoured places; in the "anywhere" places they will not grow at all. With such Roses as I named and "WILD SAVAGE" quotes on page 77 I am told that my walls are destitute of blooms for ten months in the year; but were I to plant only those which he has substituted the walls would be destitute of Roses for twelve months. I have planted every Rose named by "WILD SAVAGE" except Chesnut Hybrid, but only one blooms at all well—Maréchal Niel, the remainder being either dead or as much out of place as a savage would be tomahawking in a place of worship. If the "WILD SAVAGE" resides "where every prospect pleases," &c., he must not suppose that all men are so happily situated. The climbers named by him are an excellent selection for the tropics of England, but for the chilling eastern and the biting northern districts they are "no use at all at all."

The Roses which I named, and for the purposes and positions for which I recommended them, are incomparable. Their value lies in their hardiness and their accommodating habits. They will live and bloom and luxuriate where the Savage's tender pets would shrivel and die. I conclude by saying, Grow the pets by all means and nurture them for their delicate beauty, but do not forget the "old climbers" which flourish in spite of heat, or cold, or drought, or wet, or shows, or societies, or sheep, or savages.

I should like to see "WILD SAVAGE'S" church, and especially the parson. We are both of us, however, I think too much prejudiced to judge justly of each other's Roses; but lest he should think that I am afraid of his competition I will undertake to cut next summer more blooms from one tree of Amadis and send them to the Editors of the Rose journal (if their office will hold them) than "WILD SAVAGE" can cut from every tree on his church.—A PARSON'S GARDENER.

BARBAROSSA GRAPE.

"J. W." (page 53) asks for information about this Grape, and I very willingly give him my opinion of it. I consider it to be a very excellent late Grape, and is not so much grown as it deserves to be. Those who often fill whole houses with Lady Down's and Alicante make a mistake in not planting Barbarossa as the principal sort. It may be described as a very robust grower, producing bunches as a rule double the size of any other variety. The flavour is excellent when the fruit is thoroughly ripened, and it keeps plump and fresh until March. The berries are thin-skinned. They do not become tough like some others, nor do they lose their flavour or size through hanging long on the Vine. The bunches generally weigh from 3 to 8 lbs. Some consider the latter size too large for the table, but if necessary one big bunch can be made into two or three little bunches by cutting off the handsome shouldere.

I have never had the slightest difficulty in growing this Grape to the best advantage, the bunches having always been produced in abundance, and the berries have never failed to finish well. I am never later than the 1st of March in starting

the Vines into growth, and from then until the end of September Barbarossa has plenty of time to ripen its fruit and thoroughly mature the wood, which is an important matter. My advice to "J. W." and all others planting late Grapes is to plant Barbarossa by all means, not as a "single cane at the end of the house," but as the "main crop."—VITIS.

As information is sought on the above Grape I desire to say that six years ago I made a small addition to the late vineery. A Barbarossa and Muscat of Alexandria were planted in a good border, and the former grew so vigorously that the second year after planting I trained two more shoots from it, and gave it three rafters of the house to fill. The third year two bunches were cut from the Vine, the fourth year six, the fifth twelve, the sixth fifteen, and the heaviest bunch was 7 lbs. weight, the lightest 2 lbs.

The Vine has been cut well back, and is not at the top of the house as yet. In my opinion it is a Vine that must make plenty of wood to do well, and I intend to train it on the long-rod system. The leaves are large and downy; bunches very large and rather loose; berries somewhat oval, black, and juicy; in flavour not equal to the Black Hamburg, but it is a good late-keeping Grape, indeed one of the best. The bunches have a noble appearance on the table, and have been much admired.—F. FETCH, *Gardener, Whitfield Hall.*

THE COMMON LILAC WHITE BY FORCING.

PERHAPS there is no other flower so deliciously fragrant during midwinter or early spring as the Lilac when forced in darkness; and as it is so easily attainable, and within the reach of all who are in possession of a Mushroom-house or heated shed, or, indeed, a stovehole where light can be excluded, we have often wondered why those who appreciate sweet-scented flowers should not have extended their practice more generally than is the case to this method of Lilac forcing.

It is true that when plants are subjected to a high temperature in a dark house or shed they are afterwards useless, but we feel certain that the yield in beautiful flowers will treble compensate for the original value of the plants. Lilac flowers produced in this way are held in such high esteem with us that we have had a little house specially fitted up for the purpose, so that we have little difficulty at any time, with two or three weeks' notice, in obtaining a basketful of these truly beautiful snow-white flowers, two or three sprays of which will perfume the whole air of a room for days. Our house is merely an old shed with a closely hatched roof; but we have taken care to have efficient heating power, so that, if necessity requires it, we can raise the temperature to 100° in a very short time. Such accommodation is of course ample; indeed it is special, and is not absolutely necessary, though it reduces trouble to a minimum, and is cheapest in the end. We have managed to effect the same purpose by partitioning-off heated structures in out-of-the-way corners with success, varying according to circumstances connected with the atmospheric conditions of the houses in which the forcing was being carried out. Our practice is as follows: In the autumn we examine our shrubby borders, and endeavour, as far as possible, to select the requisite number of plants from places where overcrowding is most apparent, and where a thinning-out is most likely to do good, choosing bushes which are conspicuous for prominent well-developed buds, which must be partially cut round some time previous to being lifted in order to prepare them for early work. It must be borne in mind that unless the buds are bold and prominent, and the flowers present in embryo, any attempt at forcing will be futile. We have tried young plants from the nursery more than once, but have always failed. Young trees seem to lack stored-up vitality or stamina to undergo such an ordeal of forcing in the absence of light, and disappointment will be the only result that can be expected from such a selection. To our mind nothing can go further to exemplify—if exemplification is needed—the quantity or power of stored-up nutriment in deciduous trees, than to see one of those glorious bushes literally covered with wreath after wreath of flower, without any indication of growth in the shape of young shoots and leaves; for if forcing be conducted slow enough to allow of young shoots being pushed, or even simultaneous action of leaf and flower, the latter will be little worth. It will thus be seen that success lies in rapidity of action, provided also that the material in hand be in all respects suitable for such forcing.

As the season advances, the progress of advancing vegeta-

tion renders forcing less risky. From this date (January 3) a fortnight or three weeks at the most will be sufficient time to allow from the time the plants are introduced into heat till the flowers are ready for cutting. The syringe may be freely used at first, and heat gradually applied according to the progress made, but a dry atmosphere must be maintained as the flowers expand or they will damp-off in a few hours, and when damping-off sets in, no treatment seems powerful enough to counteract the evil.

We have a nursery of the variety known as Charles the Tenth, in an open favourable situation, and from which all suckers are removed as they appear during the summer, and they are lifted annually so as to prepare them for this system of forcing. When we think these young trees are well up to the mark for forcing, we anticipate results in proportion—perhaps in excess of our labour. An error too commonly made is to mistake the Persian Lilac for the old common one; but the Persian will not submit to forcing in darkness.—W. HEND (in *The Gardener*).

A GOOD OLD ROSE.

I KNOW of one Rose, and only one Rose, that will answer all the requirements of the description of your correspondent Mr. Edward Luckhurst, and that is Gloire de Dijon, without doubt the best Rose for all purposes that exists. I know of no other that will approach it. Only obtain a crimson Gloire de Dijon, and in my opinion you will have attained perfection. I did not answer to the Rose election, but why the "Gloire," the old Rose, was left out in the cold at the last is beyond my comprehension. The best of the others fails and pales by comparison with my old friend. This last season I have had blooms from April to January, and to-day (February 4th) I picked from the front of my house (aspect due south) a full-blown Gloire de Dijon that would not disgrace the flowery month of May.

I yesterday gathered a Camellia grown in the open air, without its having had any protection whatever in the shape of glass shades, matting, roof-shelter, &c.—A SUBSCRIBER, *Gosport.*

AURICULAS ATTACKED BY WOOLLY APHIS.

I ASK the experience of your readers on the following point. My collection of Auriculas has apparently wintered well, and now with healthy hearts the plants are beginning to show signs of a start, so I have taken a few in hand for the commencement of top-dressing, but the first disturbance of the soil has revealed an unexpected enemy.

The roots are abundant, and as usual spread and lace themselves vigorously on the interior surface of the pots; but here, against the crocks, they are attacked by colonies of what appears to be, or at least superficially resembles, the white woolly aphis of the Apple, commonly called the American Apple blight. The insects are numerous, small, sluggish, and surrounded by a white woolly substance, and though I cannot detect that they have yet done my plants any injury, I am nervously jealous of their presence. Three or four years ago the Apple aphis attacked my Apple trees, but one application of Gishurst compound with a scrubbing brush abolished him. Can it have gone from Apple boughs to Auricula roots? and if so, would Gishurst hurt the tender roots, which ought now to be ready for the spring time to call upon their vigour?

Yesterday on detecting the enemy I applied some soft soap and water, which has put him to flight, and to-day there is no trace of the pest in the pots so treated; and I think of trying the Gishurst well diluted, but shall be glad to hear the opinion of others on the enemy and remedy, for I fear my whole collection is likely to be more or less affected, and I am ignorant of the extent of the danger to which I am exposed.—JOHN T. D. LLEWELYN.

[I would counsel your correspondent, who reports the existence of woolly aphis in the soil and crockwork of his Auricula pots, to spare no pains to destroy what is sure to prove an enemy. It will not long confine itself to its present position, but will proceed to attack the strong roots and fibres of the plants, on which these mealy insects fatten fast, and along which they will spread under cover of their peculiar woolly-looking shelter.

With this nasty insect among Auriculas I have myself had no experience, and but short acquaintance. Until last year, when I saw it in two collections, I did not know it would infest these plants, and but for your correspondent's letter I should

not be able now to say more about this thing than I was a few months since in the course of some notes on *Auricula* culture in the pages of the "Florist and Pomologist." Mr. Llewelyn's information upon woolly aphis is the latest that has reached me, and it is of value.

On first noticing this insect among *Auricula* roots, and intuitively, of course, for an enemy, I could do no more than suggest a cause and a cure. For the cause, that perhaps some leaf soil or soil from the neighbourhood of infested trees has been used; and Mr. Llewelyn states that he has had this mealy bug among his Apple trees. As the creature is clearly able to exist either above or under ground, and to either live on leaves or feed on fibres, it may have got into communication with the *Auricula* through the soil direct or by emigrating from infested trees.

As for the cure, there can be but one, and that—extermination; and I had suggested turning the plants out of the soil and washing them, root, and stem, and leaf, in a solution of soft soap and water. Mr. Llewelyn states that he has applied this, but simply as a watering upon the soil, and it is even thus successful. If I say I am glad to be thus far confirmed in what I thought would be best to do, your correspondent will not think that I only mean "Sweet are the uses of (another man's) adversity."

The question is asked whether Gishurst compound, which is found very effective against woolly aphis on Apple trees, might not be used for ridding *Auricula*s of the same pest. For two reasons I would answer, No. 1st, Because I do not exactly know what the celebrated compound is made of, and I would never try a general experiment with mysterious condiments upon valuable plant life. 2ndly, Because the cheap and homely, simple and invigorating solution of soft soap is enough.

For Mr. Llewelyn's affected plants I would not recommend less than I should do myself for my own were they in a similar case. I should not, then, be content with watering the soil with soft-soap solution, fearing that that woolly wrapper may be only too good a preservative of embryo, if not of perfect, insect life. I should be content with nothing short of fullest measure. I would wash in the soap solution the roots and stem, and indeed the whole of an infested plant. I would altogether burn the infested compost, and I would replot the diseased plants at once in a compost gathered far from tainted sources. I would have the frames cleaned thoroughly, and the pots purified in scalding water, and with fresh ashes and tile laths for the plants to stand on. I would leave nothing about them wherein the mealy pest could lie concealed in any stage of life. I have a lively horror of this insect, and such dread of any nearer and dearer acquaintance with it that I jealously examine every strange plant that may come to me from collections with which I am not very familiar.

It is, of course, a pity to have to disturb well-established plants now; but the roots are beginning to be very active again, and there is no great increase of foliage yet to be distressed. It seems to me a lesser evil than allowing the spread of this loathsome pest upon the roots.—F. D. HORNER, *Kirkby Malzeard, Ripon.*

CLIVE HOUSE SEEDLING GRAPE (SO CALLED).

That which I requested you to insert in the *Journal of Horticulture* regarding this Grape I reiterate without fear, having no interest to serve but what I previously stated. For somewhat more than forty years I have been in the habit of paying a visit to the gardens at Alnwick Castle more than once every season, and by the different gardeners employed there during that time I have had every facility afforded me for seeing all that was considered worthy of notice. I distinctly remember having the seedling Grapes (of which that in question is one) pointed out to me. I afterwards frequently examined them, and when they began producing fruit had much pleasure in tasting and comparing it with that of older Vines. Not, so far as I remember, have I ever heard the Grape called by any other name than "Caseley's Seedlings," and that not only during the last summer, as Mr. Bell asserts, but for many years previously.

Having, as I consider, said quite enough about this affair, I now take leave of it.—ROBERT BOWIE, *The Gardens, Chillingham Castle.*

I SHOULD not have taken the least notice of the above had my name not been dragged in amongst other mis-statements of Mr. Bell in the *Journal*. I can only say that I corroborate

every word that my friend Mr. Bowie says about this Grape in your issue of the 18th, who knew the Grape for years before I ever saw it. If seedling Vines had ever been brought to this place they were never seen or heard of by anyone here as far back as I can trace. I have ample proofs that the Grape was raised by Mr. Wm. Caseley in this garden some twenty years ago, and it has been grown and fruited here ever since. How it can now turn out to be a new Grape and a Clive House Seedling are problems I leave the horticultural public to solve.

The other Grape alluded to by Mr. Bell as not securing the same honours that his adopted child did from the Fruit Committee of the Royal Horticultural Society, was simply because it was thought by some of the Committee that the flavour came too near the Muscat flavour of that excellent Grape Mrs. Pince to be distinct.—ALEX. INGRAM, *The Gardens, Alnwick Castle.*

[No more need be published on this subject.—Eds.]

WEST'S PATENT ADJUSTABLE TRELLIS.

This trellis was exhibited before the Fruit Committee of the Royal Horticultural Society on June 8th, 1876, by Mr. W. McGrath Compton, *Hibernia Wharf, London Bridge*, and was considered to be an ingenious contrivance and worthy of trial by those cultivating Vines and Cucumbers.

The patentees submit that "by the use of this trellis such portions of a Vine or its produce as are inconveniently placed are rendered moveable, so as to be brought within easy reach

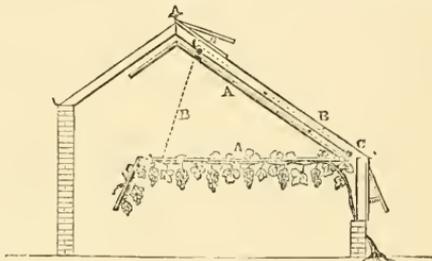

Fig. 13.

Fig. 14.

for the various purposes of thinning and cleansing, gathering the produce, or any other object for which facility of access is desirable. The trellis can be moved gently to any suitable position. It is adapted for training creepers, &c., in the conservatory and on the walls of dwelling houses, and can be readily put up or taken down, and affords every facility for cleaning or painting the sashes or wall against which the trellis may be placed. The lowering of the trellis cannot in any way injure the stem of the Vine if trained as in the drawing, the deflection being very slight. The trellis may be constructed of either iron or wood. When made of the former, which is preferable in many respects, it combines lightness of appearance with strength and durability, and can be fitted to any shaped house. Vines covering a lineal space of 60 or more feet may be lowered singly or together by turning one handle. In the drawings, A A shows the trellis in position and lowered; B B the chains for lowering and raising; and C C the drums and pulleys round which the chains work. D D shows the form and construction of the trellis. The cost of the trellis is inconsiderable, not exceeding 3s. 6d. per foot, including all fixtures. It varies according to the build of the house in which it may be fixed; but when compared with the trouble saved and advantages gained by its use, the outlay appears insignificant."

SOUVENIR DU CONGRÈS PEAR.

AUTUMN Pears are so plentiful and generally so good that a new variety must possess special merit to command approval. The Pear mentioned is, I believe, a comparatively new variety,

yet sufficiently old to have proved its worth. I planted a tree of it in 1872, and since it has borne fruit of such splendid appearance and of such superior quality I cannot help regretting that I did not plant two trees instead of one. I do not assert that it surpasses Williams' Bon Chrétien in flavour, because I believe that good old Pear when in its best condition is unsurpassable; but Souvenir du Congrès is equal to the favourite variety named, and is somewhat larger than it. I find the new Pear, therefore, equalling the old variety in one quality and surpassing it in another. The new also conveniently succeeds the old in the period of ripening. Souvenir du Congrès ripens more slowly and keeps longer than Williams' Bon Chrétien, and the popular name—"Late Williams"—that is being applied to the new Pear is, I think, appropriate.—**A FRUIT-GROWER.**

EXHIBITION PANSIES.

As planting time will soon be here, and as the improvement of this, at one time, favourite flower has been very rapid of late, a few words upon the subject may be not unacceptable to your readers, more especially as so little is said in horticultural journals of the cultivation and exhibition of this modest flower. It has often occurred to me that in the race after Roses too little attention may be paid to other less pretentious but still beautiful flowers, and it were well if some "WYLD SAVAGE" would leave the woods and champion less fashionable kinds.

The Pansy in particular has suffered from neglect, and in many—very many—schedules its name is not to be found. Why this should be so I do not know; but so it is. Our canny friends "o'er the border," however, show no such indifference, and their National Pansy Society, judging by the vitality shown every year, will long keep alive the interest in the old "Heartsease."

Then, again, a strong prejudice exists amongst English florists against the fancy Pansy, or so-called Belgian varieties; and in some cases the florists carry it to an absurd length. I had a narrow escape of disqualification at the Nottingham and Midland Counties Show last year because my pan contained some of the "irregulars;" but a reference to the schedule satisfied the judges, and I took first from twelve competitors who had confined their selections to the orthodox white and yellow grounds and selfs. To restrict an exhibitor to "show" flowers is to rob the pan of that distinctness which should appear in every collection; but I am pleased to say this prejudice is not so deeply rooted as it once was, and in many catalogues of florists' flowers "fancies" are now included, and this result has been brought about by the most legitimate of all means—the surpassing beauty of the blooms themselves. No one, however strongly wedded to the old school, could long resist the claims of a flower like Leith Walk Hero, sent out last year by Messrs. Dickson & Co. of Edinburgh, with its solid violet-purple blotches, edged with carmine on all the petals; and a well-defined creamy white margin round each blotch; or of William Melville, sent out at the same time by Messrs. Downie and Laird, also of the Scottish capital, its back petals being of rosy purple with fine dark blotch, and edged all round with yellow. Than the two named none could look more beautiful or distinct; but I could mention many others of high merit, such as George Wood, the Hon. Mrs. Beaton, John Currie, Mrs. Crawley (a dark rosy flon, edged all round with a clear margin of pure white), Bonnie Fishwife (maroon, soft violet-purple blotch, solid yellow eye, white brow, and primrose margin), Queen of Yellows, Isa Hampton, Katie Elliott, Miss Murray (rich carmine, violet-purple blotch, deep yellow eye, white brow, and pale yellow edge), Adonis, and Hector (heavy blotch of bright purple on the three under petals, with pure white lacing, and upper petals edged and streaked with rosy purple). The whole of the above were sent out in 1876, and besides being distinct fully reach the standard as regards form and substance. Because they are new I do not praise them, nor do I praise them at the expense of the older sorts, some of which will long retain their places in select collections. Of these Kirbie, Miss McNutt, Wonder, David Smith, J. B. Downie, Mrs. Neilson, George Vair, William Baird, P. W. Fairgreive, Rev. H. H. Dombain, Thos. Grainger, Colonel Wedderburn, David Dickson, Gretchen Redraes, Duke of Edinburgh, Gaiety, and W. F. Gunn are well worth growing, and would form a choice collection in conjunction with the new varieties enumerated.

Thus far I have only written of fancies, and, fearing I have

already occupied as much of your space as you can spare, shall reserve my remarks upon show Pansies for another article.—**M. H. MILLER, Leek.**

A COLLECTION OF SELECT FRUITS FOR A SMALL GARDEN.

I HAVE lately been asked to make out a list of fruits for several amateurs; and as it appears that information of this kind is wanted before the planting season closes I send the following list of what I selected some years ago privately for a reader of the Journal, who has since told me they have given great satisfaction.

Grapes.—Early: Black Hamburg and Buckland Sweet-water. Late: Lady Downe's Seedling and Barbarossa.

Peaches.—For succession: Early York, Royal George, Nobleesse, and Walburton Admirable.

Nectarines.—Elruge and Violette Hâtive.

Apricots.—Oullins Early and Moorpark.

Figs.—Brown Turkey and White Marseilles.

Plums.—Green Gage, Kirke's, Coe's Golden Drop, Goliath, Victoria and Dmsion.

Apples.—Kerry Pippin, Keswick Codlin, Lord Suffield, Blenheim Pippin, Hawthornden, Bess Pool, and Golden Harvey.

Pears.—Jargonelle, Williams' Bon Chrétien, Louise Bonne of Jersey, Marie Louise, Glou Morcean, Winter Nelis, and Beurré de Rance.

Cherries.—Royal Duke, May Duke, and Morello. *Strawberries*.—Keens' Seedling, Vicomtesse Héricart de Thury, Elton, and Dr. Hogg.

Raspberries.—Carter's Prolific and Fastolf.

Gooseberries.—Ironmonger, Red Warrington, Early Sulphur, Hedgehog, Keepsake, and Thumper.

Currants.—Red: Ruby Castle and Red Dutch. Black: Black Naples. White: White Dutch.

The above is very brief: so much the better. It is a great mistake to plant too many varieties of fruits about a small garden. If any of your correspondents should feel inclined to criticise the above let them substitute sorts for those named, with their advantages, and not add to them.—**PRACTITIONER.**

CHISWICK.

THE ROYAL HORTICULTURAL SOCIETY'S GARDEN.

"WHAT'S going on at Chiswick?" is a query frequently addressed to those who are supposed to be able to answer it. There can be no doubt whatever that the "old place" possesses a sort of evergreen interest for most people who are connected with horticultural pursuits, and "What's going on at Chiswick?" becomes therefore a very natural question.

The attention directed to Chiswick is not wholly founded on old associations, old experiments, old triumphs. There is a lingering power about these it is true, but the work of the present absorbs more of public attention than the history of the past. Than the work of the past few years no "Chiswick doings" have been more really useful. The vegetable trials have afforded instruction to all—sound reliable instruction both as regards the nomenclature and qualities of the stocks submitted for trial. That, however, belongs to the past, the very immediate past, and "What's going on now?" is the primary question with many.

Well, the work now, that is since the beginning of the year, has not much of the picturesque about it, nor is it—in one sense at least—particularly profitable. Pumping water out of stoke-holes is not very scientific employment, but such work has been a prime necessity of late in order that the other work could progress satisfactorily. On account of the inclement season much outdoor work, as is the case in many other gardens, is more or less in arrears. It has been until very lately impossible to proceed with digging, &c., and some pruning remains to be done. Yet many of the trees are pruned at Chiswick, and fine examples several of them are. The pyramid Pears, for instance, afford a lesson in management worthy of being followed. Many of these trees are about 15 feet high and from 4 to 5 feet in diameter at the base, yet so open are the branches placed, and so strong are they withal, that a man might pass between them and climb to the tops of the trees without breaking the main branches. They are now subjected to the closest of close pruning, but are not pigmy trees; on the contrary, they are stout timber trees bristling with spurs. The collection of Plums is a large one, handsome

young specimens which are each year laden with blossom, which is, however, generally destroyed by frost, the situation not being suited to Plums. Apples as a rule grow too strongly in the clayey soil of Chiswick, and in such soil the less pruning the better, perhaps, where a maximum amount of fruit is required. One more instance that a hard-and-fast rule for pruning cannot be laid down as the "best" for all situations.

A fine wall of diagonal-cordon Peaches is worthy of notice. A great number of varieties are planted, the main branches being trained 2 feet apart. The trees are not managed on the close-pinching short-spur system, but the wall space between the main branches is sufficient for the laying-in of young wood from the upper surfaces of the mains—a quick mode of covering a wall with trees easily managed and in a state capable of bearing superior fruit. There are vertical cordons of Cherries, Apricots, and Plums managed on the spur system, and in an admirable bearing state, also a collection of Vines on one of the walls; the best sorts for that mode of culture being the Eperons (Espiran) and Royal Muscadine.

In the glass department, which is extensive, work is well forward. The orchard house is highly promising, the two rows of standard Peach and Nectarine trees being in splendid condition. The branches are thinly disposed and are extremely fruitful, the blossom buds swelling rapidly. The borders in which the trees are growing are never dug—not even pointed-up with the fork; they are about as hard as a gravel walk, and are heavily dressed with manure during the growing season, which induces a network of fibrous roots—the sequel of fruitful branches. Potted trees are similarly promising, some of them just expanding their blossoms; even amongst trees packed in fern in the open air are one or two Apricots fully in flower, suggestive of the earliness of the season and what may justly be termed its dangerous character in reference to the fruit crops.

In the vinerias the canes are at rest. At Chiswick fuel is economised, the Vines being grown almost entirely with sun heat. The collection of Grapes is the most extensive in the kingdom. It is not necessary to dwell on the varieties, but as information has been sought on Black Barbarossa (Gros Guillaume) it may be stated that it is one of the freest bearing and finest Grapes in the collection.

In the large vinery, a noble structure, Camellias, Rhododendrons, &c., are arranged. These plants are not half so large as they were a few years ago, but are infinitely better, being well furnished, healthy, and well set with buds. Their present condition is mainly due to severe pruning. Camellias and Rhododendrons may be cut as severely as Pelargoniums, and, like them, are the better for it; the shrubs mentioned "break" out of the old wood as freely as does a Thorn hedge after it has been "plashed" or "scotched."

Flowering and other decorative plants are also plentifully represented—some just unfolding their flowers, others being grown for experimental purposes. Amongst the latter may be instanced Epacris, a collection of which the Council are establishing, and of which something useful will be said in due time. The flowering plants include Lillaes, Azaleas, Prunus sinensis, Coronillas, Primulas, Echeveria retusa, &c., and as particularly noticeable Lily of the Valley. The Lily crowns are grown at Chiswick, and it is not possible to imagine that imported "clumps" can excel them. The system of preparing them is to afford an open position, plenty of room, rich soil, and heavy mulchings of manure. By this plan small tufts become in three years bold flowering crowns, which are dug up and packed in cocoa-nut fibre in a heated place, and almost every crown produces a vigorous spike of flowers.

In one of the pits are a few Orchids, also Ferns. Amongst the latter *Pteris acrostichata* major is distinct and fine; it is of easy growth, and very valuable for decorative purposes. *Nephrolepis davallioides* furcata, lately sent by the Messrs. Veitch, is also attractive by its glossy and gracefully arching fronds. Noticeable in the stove, which is mainly occupied with Palms and other ornamental-foliaged plants, are two fine baskets of *Torenia asiatica*. This is a good old plant, and that is the proper way to grow it and show it to advantage. Many of the decorative plants at Chiswick will probably be removed to the conservatory at South Kensington to aid in making attractive the meeting which is announced to be held next week: where the plants now are few can enjoy them.

Let South Kensington be what it may, one thing is clear—that any society possessing Chiswick, its ten acres of ground, its extensive ranges of glass, its great collection of fruits, its multitude of plants, its facilities for experimental purposes,

and (although he will not thank me for saying so) its able superintendent, has a rich horticultural store, and an immense advantage over any "new society" which a few good people "see in their dreams."

Much has gone on during the past, is going on at the present, and in all probability will go on in the future—"at Chiswick."—J. W.

KITCHEN-GARDEN NOTES.

WITH February begins the busy season in the kitchen garden. Up to this time unfavourable weather hinders many from doing much in this department, and this may be the case without any severe loss following; but let the weather be what it may, an exertion must be made now or many crops will be so behind that no amount of after-attention or hard work will remedy.

Before putting in any crop the ground must be well prepared. This is of great importance, and no half-done work should ever be allowed. Where the subsoil is cold and clayey too much of it must not be turned up in one season. Some crops of a rough-growing description might thrive in it, but small seeds and plants will perish or fail to come to perfection. Soil that is turned up stiff in trenching I always make a rule of planting with Potatoes the first season, and when properly manured any crop will grow on it afterwards. One of the best manures for a newly-exposed stiff soil I find to be decayed leaves, to be followed with something of a more lasting nature the following season. All ground for vegetables should always be turned over and left quite rough at first. Some make it smooth on the surface with the spade, because it will soon be planted. This is a mistake. Ground treated in this manner becomes quite bound on the surface after the first heavy shower, and the non-rising influence of the atmosphere has no further power. When left rough even for a day or two and then broken up with a fork the result is quite the opposite.

All kinds of Cabbage, Kale, Cauliflower, &c., grow best in a rich soil, but there is a possibility of making it too rich, not only for the crops named, but also for such as Onions and Celery. Too much manure makes them large enough, but they want substance; on the other hand, too little manure is the cause of their being tough and dry, and very often small. The plan I find most satisfactory is to give a moderate dressing of manure annually. Excepting in such cases as mentioned above leaves should never be used alone as manure, but mixed with decayed cow dung or stable litter they are excellent for all crops. In most small gardens the ground will be all cleared by this time. Any Kale or Broccoli remaining should be lifted and laid-in in some odd corner.

Before putting in any crops write labels for every kind of vegetable that is to be planted, and then go over the garden from one end to the other and place a label in wherever its crop is to occupy. This I was taught when "serving my time" with one of the "old school," and have practised since with a saving of much confusion.

Rotation of crops is by some considered indispensable, but it is not absolutely necessary to insure success. The following is something like the way I try to work-in my crops:—Celery in the strongest soil in the garden. This is thoroughly manured with the best "muck" obtainable. When the Celery is cleared off the ground is turned over, without adding much manure, and here the Onions are sown. Cauliflowers succeed these occasionally, but when the Onions can be harvested early enough the ground is manured and turned over at once and filled with autumn-sown Cabbage plants. These I always like to follow with Potatoes, and Potatoes with deep-rooting crops, such as Carrots, Beet, and Parsnips. Potatoes open the ground for these crops, and they do not harbour so much vermin in the soil as many others. Broccoli requires an open but rich soil, and it need not be planted in the lightest situation. Brussels Sprouts thrive under the same conditions. Rhubarb I always plant in the most shaded situation. It does not become quite so fine here as in a fully exposed place, but it does better in the shade than most other crops.

Excepting what is forced under glass, I do not advise putting any kind of seeds into the ground until the first or second week in March, and unless the weather is favourable and the soil in good condition nothing is lost by waiting a week or two longer. I have sown Peas in February and again at the end of March, and the latter were ready for use quite as early as the former. Where the garden is large enough to admit of it, or rather where there is a sunny south border, all early

vegetables, such as Cauliflowers, Horn Carrots, Turnips, &c., should be sown in small quantities here until those in the main quarters come in.—A KITCHEN GARDENER.

TOOTHED CLUB MOSS—*LYCOPodium DENTICULATUM*.

OUR Club Mosses are a race of plants found in spongy boggy places in upland and mountainous districts; many find their way to us from other countries and have long graced our stoves, greenhouses, and exhibition tables. The *Lycopodium* are intermediate in appearance between Mosses and Ferns, and are furnished with spreading or creeping stems. We are told that the powder contained in the capsules of *Lycopodium*

Fig. 15.—*Lycopodium helveticum*.

clavatum is inflammable and has been used in fireworks. L. Selago is used in dyeing to fix colours, and is employed by some as an emetic and cathartic, but requires care in using. Linnaeus says the Swedes use a decoction of it to destroy lice on swine and other animals. *Lycopodium* are neat evergreen Moss-like plants. Many of them when once established are as troublesome as weeds, especially in moist warm places. They may be cultivated in Warden cases, pots, baskets, aquariums, and rockwork. They are increased by division and cuttings in the spring. Though moisture-loving plants they enjoy thorough drainage, and well supplying with water and pure air. A mixture of sandy loam and well-decomposed vegetable matter, with pieces of sandstone and charcoal dust, will meet their requirements. *Lycopodium helveticum*, of which we add a woodcut, is a native of Switzerland, and requires the same treatment as *L. denticulatum*.

L. denticulatum has during late years become one of the most popular of decorative plants, and is grown and sold for this

purpose by many thousands of dozens annually. For forming fresh green fringes in almost any temperature, and a close yet elegant ground-covering in conservatories and halls, it has no superior. It is a most accommodating plant, luxuriating in the high temperature of the stove and the drier cooler air of the greenhouse; while it endures better than most plants the draughty and semi-dark corridors of the mansion. For shaded rockwork under glass it is indispensable, and, as has been lately stated by Mr. Luckhurst, it will grow well in shaded places in the open air, receiving little, if any, injury from the frosts of ordinary winters. It is, in fact, a hardy sub-alpine plant, a native of Switzerland, and from whence it was introduced about a century ago. It is, however, most commonly grown as a cool stove plant, and when it is required to be increased rapidly, and plants are desired to be established quickly, a genial temperature must be afforded. When plants are prepared for decorative purposes, pots of a convenient size are filled with sandy soil, and a few sprays are placed in the centre of each pot, pressing them down with a little soil placed over the lower portions of the stems, leaving the surface of the soil rounded and rather high in the centre. Water can then be sprinkled freely over the plants, which they rejoice in; but they cannot endure stagnant soil, hence the advantage of "high potting." In all places where much plant-decoration is required, this familiar, pleasing, and tractable *Lycopod* should be largely grown.—N.

NETHERBY HALL,

THE SEAT OF SIR FREDERICK ULRIC GRAHAM, BART.

By the old highway between the two capitals there are few, if any, spots which have won so many panegyrics from travellers as that part of the vale of the Esk lying between Langholm and Longtown. To the traveller by rail, however, the greater part of this scenery is lost as the branch from Langholm diverges to the east of the vale; but to those to whom time is not a special consideration the balance of beauty lies decidedly on the side of the old coach road, a consideration which induced me when paying a visit lately to my friend Mr. Kerr, gardener at Netherby, to sacrifice time for pleasure; and I had certainly no cause to regard the time as mis-spent, neither do I consider that the rambling notes which I took of the scenery will be uninteresting to the readers of the Journal.

Langholm is a prosperous little town, well worthy of notice not only for its enterprising manufacturers and world-renowned tweeds, but also for the beauty of its surroundings, for it nestles at the feet of a circle of bold wood-fringed hills which environ it; and being situated at the point where the vales of the Esk, the Ewes, and the Wanchope meet, it forms a very pretty picture indeed. On leaving the town proofs of its prosperity are springing up on all sides in the form of chaste villas and spacious mansions. One in particular deserves special notice from gardeners—Brooklyn Cottage, the residence of Mr. Park, who, along with his brother (whose place I will notice by-and-by), after a successful career as florists in America, are spending in independence the evening of life in their native vale.

A mile or so below Langholm a substantial bridge bears the road across the river, and the view from it is very picturesque, with the town and its environs in the background, and in front the river foaming, chafing, and dashing over its rocky bed past an old distillery, the booming of whose condenser is heard above the sound of the chafing waters. The road now enters what is called the Dean Banks, and for two miles is overarched by magnificent trees. The Larches here are said to be the oldest in the south of Scotland, and judging from the few that remain giant specimens they must have been, but most of them have of late years succumbed to the woodman's axe. Many of the Spruces are a noble sight as their great dark masses tower up against the deep blue sky. Did time permit, an hour or two could be very profitably spent here among the Ferns and other plants which flourish in great abundance.

Proceeding for a mile or so through this spacious avenue you pass Broomholm on the east side of the river. It occupies a fine situation, but the mansion has been built in the olden times when comfort and convenience were not sacrificed for appearance. It has for upwards of two centuries been the residence of the Maxwells, a branch of the powerful border clan of that name, whose title to the Broomholm estates dates back from that period. They were the founders of Langholm; that part of it on the east side of the Esk stands on their

estate. A short distance above Broomholm there is a grotto upon which much labour has been bestowed. It is a rocky island, and is reached from the east side of the river by an iron bridge. It is a secluded and romantic spot surrounded by deep woods and well worth a visit. From Broomholm to Netherby "the Buccleuch" is "monarch of all you survey;" and on emerging from the avenue you come upon Irving House, the residence of his Grace's chamberlain, a mansion worthy of a Duke. The garden is close to the public road, but merits no special notice. There are some grand old trees about the mansion, highly appreciated apparently by a colony of rooks. The Esk, which here makes a graceful sweep round the grounds of Irving House, is joined by the Larras, a dark rugged mountain stream that comes tumbling down a deeply wooded glen; and high above the topmost trees are seen the arches of a magnificent viaduct traversed by railway trains in their journeys to and from Langholm. The next object that catches the eye

is a grim old Border Keep. It is the only one in the locality that has been spared, but you cannot look from that relic of antiquity to the commodious if not elegant homesteads nestling all around without exclaiming, "Say not that the former times were better than these." The road and the river which had parted company again converge, and on passing a group of cottages with the addition of a good meal mill you reach the far-famed Gilnockie bridge, and here the scenery is such that it cannot be dismissed with a casual notice.

The appearance of the river as it rounds a sharp curve above the mill and comes tumbling over horizontal beds of limestone, and chafing against the cliffs that are overhung with stately trees, with the hills, the wood, the homesteadings, and the old Peel tower in the background, form an exquisite picture. Nor is the scenery on the south side of the bridge less striking, for you look down upon a wild mass of limestone boulders through which the river sweeps in many dark eddies, while

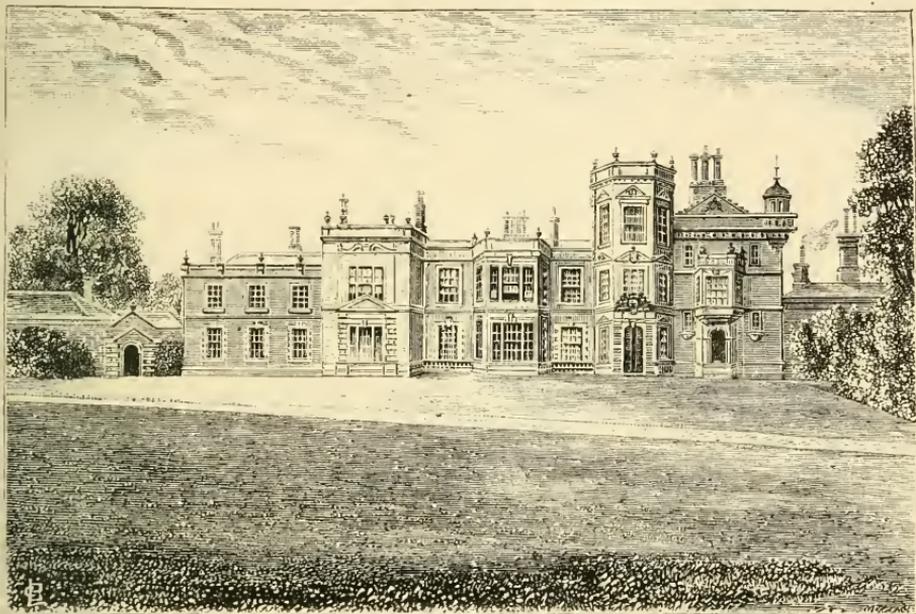

Fig. 16.—NETHERBY HALL.

among the great blocks on the precipitous western bank are the ruins of a bower erected by the Duchess of Buccleuch. But the interest does not end here, for on examining the rocks they are seen to afford a rich field for the geologist. Here are sea shells compared with which the same species in the present age are mere pigmies, along with what appear to be exotic Ferns and other plants: but here I am out of my element, being better acquainted with the living than the petrified specimens. The river here trawls below a massive stone bridge leading over a deep romantic glen called Byre Burn. On crossing the bridge the view up the river is very fine; yet beyond that there is little that merits special notice, till again the river is crossed by an old bridge of three arches springing on the east side from a red sandstone cliff. From the bridge you see before you bold overhanging cliffs of red sandstone crowned with trees, underneath which the dark sullen river is chafing. At the east side of the bridge is the entrance into the church and parsonage of Canonbie, and I suppose a spot more fertile and fair can rarely be found, justifying the cynical observation that wherever you find a comfortable house surrounded by "pastures green" you may conclude it is a parsonage. Passing the "Cross Keys" inn that in the season is monopolised by salmon fishers, you see lying to the east of you Canonbie Lee, on which in days of yore there was racing and chasing by the mounted Grahams, Fosters, Fenwicks, and

Musgraves of the Netherby clan after the lost bride of Netherby and her brave young Lochinvar. Beyond is the Liddle advancing to join the Esk. Here the streams advance and recede and advance again towards each other, till after many whimples and windings they blend into one and roll on peacefully towards the ocean.

Beyond the Liddle lies the fair domain of Notherby, and threading down the foot of a steep wooded bank is the Border Union Railway. On the top of a steep lynn is an old fort or camp, said to be Roman. It is easily approached from Riddings Junction, and is well worth a visit. The prominent object that catches the eye is a high earthwork in the form of the frustrum of a cone. From the base of it sweeps in an irregular circle a wide deep moat and earthwork, enclosing an area of three-quarters of an acre. On the south side opposite the tower, and striking out from its base, sweep an outer trench and earthwork in the form of a crescent. Beyond these there appear to have been less trenches, and also what appears to have been a canal for filling the moats. If this was the case, then part of it must have fallen over the lynn, as the moat that runs out into it has a modern look, leading to the inference that if it was made by the Romans they were not its last occupants. It stands at a point commanding the entrance into both valleys. The view from it is extremely lovely, having the dark heathery hills of Eskdale in

the background, the level, fertile, and richly-wooded plains of Cumberland sweeping out to the south, with the belt of the Solway glistening like silver through the woods in the distance, and the massive peaks of the Cumberland mountains stretching along the southern horizon. Passing the inn a pleasant road conducts you past Woodhouseless, Woodlees, and other places well worthy of notice; but a smart-looking house catches the eye. It is the property of Mr. James Park, brother to Mr. Park of Brooklyn Cottage, and here as a country gentleman he is reaping the fruits of his professional career in America, a sight that cannot fail to arouse emulation in every gardener's breast.

Here the beauty of the scenery culminates, for there, backed by deep woods, is the mansion and grounds of Netherby, a noble pile, and worthy of the noble line that for so many centuries have been its owners. Tradition traces back the origin to the family to the darkest days in England's history—the wars between the houses of Lancaster and York. It is said that in those troubled days a knight, son of the Lord of Monteith, stung by the ingratitude of the Scottish king, for whom he had braved death in many a bloody field, left him in disgust, and with several of his clan came to the English border and took up his abode in the Debateable Land. The lands of Netherby were part of the border country cursed by being part of what was known as “the Debateable Lands.” They were repeatedly laid waste by irruptions of the borderers. James I. granted the Debateable Lands to the Earl of Cumberland, who sold them to Sir Richard Graham, and the sale was confirmed by Charles I. Since the Restoration the lands have been at peace. Netherby was a Roman station, as is testified by the numerous coins and monuments which have been found there. The present mansion was chiefly built by Dr. Robert Graham, who died in 1782.

Around his old tower, the Ivy-clad ruins of which overlook the valley, the descendants of “the son of Monteith” grew and multiplied, and by their indomitable Scots pluck became the frontier defence of England; and in the reign of Charles I. one of them named Richard, by his winning manners and worth, became such a favourite at Court that he was created a baronet. He also obtained sole possession of the parishes of Arthurth, Kirkandrews, and part of Bewcastle. Since then the family has played an important part in the history of their country, and in latter years Sir James Graham stands out prominently in the history of the first half of the present century. The present proprietor, Sir Frederick Ulric Graham, is the eldest son of Sir James, preferring the pleasures of private life to the cares of state, and manifests a laudable interest in his noble mansion, estates, and tenantry.

My road leads down through the fields past the old tower to the side of the Esk, on the opposite side of which stood another castle of the Grahams, immortalised as the scene of Sir Walter's “Lochinvar,” and like that young gallant I must “swim the Esk river where ford there is none,” and I have no “stead” good, bad, nor indifferent on which to accomplish the feat; but through the kind consideration of Mr. Kerr, who sent a man to “boat me o'er,” which was fully more comfortable, soon I am at Netherby Hall.

Of the front view of this mansion (than which there is none more interesting, notable and beautiful in all the border land), I need not say one word, as the photograph speaks for itself, but it gives an imperfect idea of the house, which extends backwards and from which a view in many respects better than the front can be obtained. Along the back of the house is a cmented terrace 25 feet broad used as a skating rink, then a grass verge 7 feet wide. A flight of steps leads down to the flower garden, or “terrace garden” as it is called. This was executed about two years ago, and is in keeping with the mansion. During last summer the beds were very gay, having been artistically filled with bedding plants by Mr. Kerr. This garden is backed-up to the east by woods; to the west and south lies a beautiful lawn studded with magnificent Beeches, Sycamores, Oaks, Limes, Elms, and Scotch Firs. Yet I am told that little more than a century ago there was not a tree to be seen in all the locality; and it is impossible to look southwards as far as the eye can reach over the broad and fertile acres of Netherby, lying like a well cultivated garden, without contrasting the sylvan beauty of the scene with the wild desolation of the times when these naked debateable grounds were secured by the moss-troopers.

Netherby is a deeply interesting spot to the archaeologist, as the excavations made about it more than a century ago show, as before mentioned, that it stands upon what has been an

extensive and permanent Roman station. Many rare articles have from time to time been discovered, and as late as two years ago during some alterations a small Roman altar was found in a good state of preservation.

Now, with a short description of the gardens I will close the notes of my deeply interesting day's ramble in Lower Eskdale. Proceeding from Mr. Kerr's house in the direction of the kitchen garden, and passing many cold frames (which were filled with bedding and other useful plants), we come to a propagating pit, length 27 feet, width 11 feet. This is principally filled with some fine young plants intended for table-work. The second house is a quarter-span, length 34 feet, width 10 feet. This is used for growing Pines, and at the time of my visit there were some very fine fruit in it. The sorts grown are principally Queens with a few Charlotte Rothschilds. Passing from this house you enter the kitchen garden, occupying about two acres surrounded by a good brick wall, which is covered with Plum, Pear, and Cherry trees seeming to thrive pretty well. Vegetables are exceedingly well grown and merit special notice. In this garden stands the principal range of forcing houses. The first of the glass structures we enter is a Peach house, length 86 feet, width 15½ feet, filled with healthy fruitful-looking trees. I may mention, that when Mr. Kerr entered on his duties as gardener here he was very much annoyed with scale on the Peach trees, and after trying many compositions all to no effect, he resolved on trying paraffin oil, two wine-glassfuls to three gallons of water. After mixing it thoroughly with the water he syringed the whole of the trees with this mixture. The result is, he has never been annoyed with scale since.

The next house is a stove, length 44 feet, width 15½ feet, filled with a fine variety of specimens of such plants as Crotons, Palms, Ferns, Begonias, Dracenas, Bismas, &c., with *Cissus discolor* trained-up the rafters, which has a good effect. The whole are in perfect health. In passing through this house Mr. Kerr gave me what he has found to be an effectual cure for mealy bug. Thinking that it may be of use to some one, with Mr. Kerr's permission I shall give the readers of the Journal the benefit of it. To one pint of water add two table-spoonfuls of paraffin oil. After mixing it well go over the whole of the plant, leaves and branches, with a sponge.

The next house is a vinery, length 48 feet, width 21½ feet, in which the Vines look remarkably well and bear fine crops of fruit. From this we enter a greenhouse, length 37 feet, width 16½ feet. This house is filled with a miscellaneous lot of plants for house and table decoration. We then come to a vinery, length 48 feet, width 21½ feet, in which are hanging some very fine bunches of Grapes. Mr. Kerr grows all the leading sorts; his favourites are Black Hamburg, Muscat Hamburg, Duchesse of Buccleuch, Frankenthal, Chasselas Napoleon, Royal Muscadine, Mrs. Pinco, Gros Colman, Lady Downe's, Buckland Sweetwater, and Muscat of Alexandria. Waltham Cross has not come up to Mr. Kerr's expectations, and I must say that I quite agree with his opinion. It is pleasantly flavoured, but certainly without the fine high perfume of Muscat of Alexandria and several other Grapes. The next house is also a vinery, length 43 feet, width 15½ feet. The Vines in this house also look well. At the end of this we come to the last of the glass structures, which is a Peach house 44 feet in length and 15½ feet wide, filled with Peach and Nectarine trees, all in fine condition and bearing remarkable crops of superior fruit.

Midway between the house and kitchen garden is a geometrical flower garden in gravel and edged with fancy tiles. This goes under the name of Lady Graham's flower garden. It looks well at all times of the year, but decidedly best when gay with Tulips, as they show off the figures to the best advantage.

Immediately outside the kitchen garden there is a considerable piece of ground used for growing vegetables, and at a short distance from this is the orchard, unfortunately in a very unfavourable situation for fruit trees, lying low and wet. The trees are all very old and past their best. Mr. Kerr gave them a washing with lime water, and mulched them with manure a few years ago, which has assisted them greatly.

Not far from this is the pinetum, in which most noteworthy are the following trees:—*Wellingtonia gigantea*, *Abies Douglassii*, *Picea Nordmanniana*, *nobilis*, and *Webbiana*, *Pinus austriaca*, and *Thujopsis borealis*. Proceeding from this in the direction of the house, you pass a square cmented enclosure surrounded with an ornamental fence of wire netting. This is used for lawn tennis. There are many fine and pleasant walks through the parks and woods, where various grand peeps of scenery

ars to be had; but of this I have not time to notice further than saying that everything, both grounds and gardens, are in the best state of keeping.—JAMES DICKSON, *Arkleton*.

THE HERB GARDEN.

HERBS are often neglected unless a special place is set apart for them. They are indispensable to every garden and household, and perhaps a few lines in reference to them will not be out of season. I find any time during the winter suitable for dividing and planting most herbs, such as Golden, Common, and Lemon Thyme, Balm, &c. Beds should be retained for growing the annual herbs, as Sweet Basil, Marjoram, Chervil, Marigold, Borage, &c., for without a plentiful supply of these a gardener cannot keep on good terms with the cook. A few of the most useful of the herbs are—

Balm (*Melissa officinalis*).—An aromatic herb which used to be a great favourite, but is less in request now than formerly. I find it very useful for bees; it is propagated easily by division of the roots in late autumn or early spring. All the attention it needs is to cut the stems down and fork round the roots in late autumn.

Sweet Basil (*Ocimum basilicum*) is a herb which no garden should be without. It and the Knotted Marjoram are important in making mock turtle soup. A few seedlings should be raised in heat for early use.

Fennel (*Anethum foeniculum*) is one of those herbs which must have a place in every herb garden however limited. It is chiefly used for sauce and for garnishing pickled salmon and mackerel. It is a perennial, and will live many years if the stalks are cut down so as to prevent it going to seed. It is readily raised from seed, and increased by division.

Sweet Marjoram (*Origanum marjorana*) is a herb which should be allowed its necessary space in every garden, for it is at all times useful for giving flavour. There are two other sorts, the pot and winter Marjoram, both of which are hardy perennials, and are valuable and easily-grown herbs.

Mint (*Mentha viridis*) is a herb of such daily utility as to demand a place in all herb gardens. It is easily propagated by planting pieces of the root, which spread along under and over the ground. It requires a moist soil and a shady border, and is all the better for a little rich mulching once or twice a year.

Parsley (*Apium petroselinum*).—Of all the herbs in the garden there is not one which is wanted in the kitchen so often as this. It is a long time coming up after the seed is sown, often two months, and when it is up it is not of very rapid growth. Being a biennial the seed must be sown every year, and I find the plants are strengthened by cutting some of them down in the early autumn, so that they will live through the winter and give a good supply in the spring.

Rue (*Ruta graveolens*) is a bitter plant. The leaves have a very powerful scent; some persons like the flavour it imparts to tea. It is generally grown from cuttings, also from seed sown in the spring.

Sage (*Salvia officinalis*) is also one of the most useful of herbs, which must be grown in every garden. It likes a dry sheltered border. It is propagated from cuttings, also from seed sown in the spring. It is all the better for a little rich mulching as the plants grow old.

Winter Savory (*Satureia montana*) is a herb of such great utility that it can ill be spared from the smallest herb garden. It is an excellent flavourer for many different dishes. It is easily grown from seed sown in April, or from cuttings planted in a shady border.

Thyme (*Thymus vulgaris*) is also one of those herbs which must have a corner in every garden. Common Thyme grows readily from seed sown in April, and is also increased by division of the roots. Lemon Thyme (*Thymus citridorone*) is far superior to the other, and it may be increased readily by layering its procumbent branches.—H. S. J.

CHAPTERS ON INSECTS FOR GARDENERS.

No. 16.

THE somewhat singular name of "larva," which modern naturalists adopt as a general appellation for the second stage of insect life, took its rise from the fanciful notion that at this period of its history the proper insect moved about as if masked or concealed; this name, we remark, is much more applicable in some orders than in others. No one would suspect a butterfly was hidden under the cylindrical crawling

creature which is seen intently engaged in stripping the leaves from a plant or tree; but the larva of many beetles are certainly beetle-like, and the larva of a grasshopper, size excepted, to an ordinary eye is little different from the perfect insect. Rapidity of growth in the larva or caterpillar stage is also a circumstance more frequent than in several orders, and herein the butterflies have mostly the advantage of their companions the moths of the same order. It is particularly noticeable, this difference between them, in the matter of what is called "ecdysis;" the process of casting the skin, which has to befall all caterpillars a varying number of times. (One has not opportunities for verifying the fact in the case of internal feeders upon the pith of shrubs and trees, but it may be presumed these follow the general law.) A moth caterpillar seems frequently to make a great fuss in going through one of these moults; it selects carefully a place to rest upon, ceases to eat several days before, and when the change is over, does not eat for a day. But a butterfly caterpillar accelerates the business, I have noticed the common Nettle-asters (*Vanessa Io* and *Urtice*) feeding on until the old skin was wellnigh ready to burst, and a day might suffice for the whole affair. Nor do I find on record proofs that the number of these changes with butterfly caterpillars reaches that attained to by some of the moths, where eight or even ten changes have been observed, these occurring in caterpillars which live from six to nine months. The pugnacity or cannibalism, again, which is a peculiar feature in the history of some moth caterpillars, has not a parallel amongst British butterflies, which, as caterpillars, are the pink of amiability to each other, despite their spiny armour, which in some species might seem suggestive of the well-known motto attached to the Scottish Thistle, and which, in all probability, gives some hungry birds a colic!

A lady, more amusing than versacions, who wrote a once famous book on butterflies, tries to philosophise by telling us that "Nature keeps her butterflies and caterpillars locked up during the winter in their egg state," and she follows this up by the theory that the spring and summer is the great season for caterpillars, the autumn for butterflies. Now it is true that in early autumn, at a date varying with the season, there are large numbers of butterflies abroad, and there is also a spring flight of these insects, made up of hibernated individuals, or of others that have passed the winter in the chrysalis state; but it is also true that on fine days from April to October there will always be butterflies abroad, nor can we fix any particular season for the feeding of the majority of caterpillars. And as to the idea about the egg state, that is easily disproved, for, save in the small group of the Hairstreaks, it does not appear that any butterflies lay eggs in the autumn to hatch out in spring. Many butterflies' eggs, notably those laid on Brassicaceous plants, hatch in about a fortnight, so that the horticulturist who has seen any "children of the sun" hovering over his Cabbages and Cauliflowers had better look on the leaves without much delay for the minepin-shaped ribbed eggs they have left behind, if he wishes to anticipate the ravages of the future, and make their possible birthplace their tomb.

Eggs, we take for granted, cannot feel; it is doubtful whether during the winter season the pupa or chrysalis feels; hence, without hesitation, we may destroy those of the Large and Small Whites (*P. Brassicæ* and *Rapi*) to be found here and there at this time on walls, palings, and trunks of trees. Yet so strong is their vitality that during severe weather these have been found frozen hard and quite brittle, but this has not prevented the due emergence of the butterfly. And the position of the pupa marks off as distinct from the other British butterflies the few species belonging to the family of the Skippers, for only amongst these is the pupa hidden in a silken cocoon. The large group of the Exposers is capable of being subdivided very distinctly; and the first section consists of those species in which the pupa is simply suspended by the tail, and we have a butterfly with the first pair of legs unfitted for walking. Within this section are two families—that of the "Spine-bearers," where the caterpillars have spines, usually branched, and that with "Slug-shaped" caterpillars, where these are plump, sometimes a little elongated, bare or slightly downy, and with two small points projecting from the tail. The *Fritillaries*, most frequently seen in or near woods, head the first family; some of these in the butterfly state display beautiful silvery spots, the markings in the bulk of the species resembling the old-fashioned Lily so called with chequered flowers. Their period of flight seldom exceeds two or three weeks. No less than six of the caterpillars of our *Fritillaries* feed on Violets, though not on cultivated species,

and the curious spines in one or two species project over the head like horns. A familiar example is the Pearl-bordered (*Argynnis Empoeyne*) to be captured in most large woods by the score early in June. We pass from these to the more showy group of the Angle-wings, often with gregarious larvae, generally attached to the order *Urticeae*, as formerly constituted, feeding on Nettles, the Hop, and the Elm; though the Painted Lady (*Vanessa Cardui*) prefers Thistles, yet the larva will eat Nettles. These species, the *Vanesside*, as recognized even by children through such familiar names as the Peacock, the Tortoiseshell, and the Red Admiral (Admirable?) are visitors to our gardens, where their graceful and rapid movements are pleasing; nor is their abstraction of honey so carried on as to injure the flowers they frequent. The not very abundant *Comma* (*V. C. album*) it should be noted, though the caterpillar feeds on the Hop, or rarely on the Red Currant, is too slightly injurious to be reckoned as an insect enemy. Of this and the Little Tortoiseshell there are two broods each year; rearing the latter (*V. Urtice*) from the unpromising larva which swarm on Nettles in odd corners during May, and again in July, has been to many the first experiment in butterfly nurture. The pretty White Admiral (*V. Sybilla*) is, however, a lover of woods, where the caterpillar eats Honeysuckle; it was once common at Coombe Wood, Surrey, near the ground rendered famous by a nurseryman of our time.—J. R. S. C.

FRUITS IN ONTARIO.

ONTARIO is as well adapted for the culture of a great variety of fruits as any part of the world. Its climate closely resembles that of the Grape-growing provinces of the Rhine. The western portion of Ontario has been pronounced by authorities to be the most suitable part of the American continent for Grape culture. There is ample sun to ripen the fruit, and the Vines can stand the frosts of winter without artificial protection. Vineyards require too much labour for a new country, but in process of time no doubt Canada will be able to make its own wine. Peaches, Apricots, and Nectarines ripen in the extreme south and west—I mean as orchard crops. In favourable situations these fruits ripen in gardens here and there all through Canada West.

The Apple orchards of Ontario, both as regards the quantities and qualities of the fruit, are second to none in the world. The export of Apples has been found such a profitable business that farmers through the province have been adding largely to their orchards during the last few years. A ten-acre orchard is not an unusual sight, and I have seen orchards as large as forty acres. Many of the so-called American Apples that we see in the shops at home are grown in Canada. The following are some of the favourite kinds:—Rhode Island Greening, Northern Spy, Baldwin, Swazee, Pomme Grise Famense, Duchesse of Oldenburgh, Swaz, Gravenstein, Blenheim Orange, Keswick Codlin, Holland Pippin, Alexander, American Golden Russet, Red Astrachan, Ribston Pippin, Esopus Spitzenburg, and King of Tomkin's County.

The Fruit-growers' Association of Canada recommend the following varieties—viz. For summer: The Early Harvest and Red Astrachan as our Apples, and the Sweet Dough. For early autumn: The Duchess of Oldenburgh, Gravenstein, Primrose, and Jersey Sweet. For late autumn and early winter: The Ribston Pippin, Hubbardston Nonsuch, Fall Pippin, and Snow Apple. For midwinter to March: The Rhode Island Greening, Northern Spy, Esopus Spitzenburg, Pomme Grise, and Tolman Sweet. For spring: The Golden Russet and Roxbury Russet. For market the most profitable varieties are Red Astrachan, Duchesse of Oldenburgh, Gravenstein, and Hubbardston Nonsuch, ripening in the order in which they are named. For a near or home market and for shipping the Rhode Island Greening, Baldwin, Golden Russet, and Roxbury Russet will yield the largest pecuniary returns.

Apples are barrelled in the orchards and despatched there and then to market. The orchard in Canada West, with very little labour and moderate attention, is a source of a clear annual income to the farmer who possesses one. To make an orchard, 25 cents per tree is the estimated cost. The trees commence bearing in ten years. Farmers who do not like the risk or the trouble of marketing their Apples can sell them in the orchard for from \$1.50 to \$2 per barrel.

Pears do equally well as Apples, but being a tenderer and more delicate fruit they are more difficult to bring to market. The following are the chief varieties grown:—Louise Bonno of Jersey, Bartlett, Beurré d'Anjou, Beurré Clairgean, Flemish

Beauty, Duchesse d'Angoulême, Grasiin, Sheldon, and Winter Nells.

Melons, both sweet Melons and water Melons, ripen throughout Canada. The habitants of Lower Canada grow Musk and Citron Melons in their little gardens that would throw in the shade the Melons forced at great cost in good English gardens.

All the well-known English small fruits, except the Gooseberry, do admirably in Ontario. The cultivation of these fruits for market is now a very profitable business in certain localities. In the vicinity of Oakville on Lake Ontario there is a large breadth of land under Strawberries—an acre or so on every farm, and occasionally as much as ten acres. Both climate and soil in the vicinity of Lake Ontario seem admirably adapted to this fruit. The facilities for marketing fruit or vegetables either by land or by water carriage are unrivalled, and the demand for both, but especially for Strawberries, seems to be unlimited in the eastern states. The capital required for small fruit farming is not large, and I know of no way in which an industrious immigrant with some knowledge of this species of agriculture could do better than by buying a small farm in Ontario and devoting himself entirely to fruit-farming. He might, along with Strawberry plants, plant Apple, Pear, and Currant trees, which would be an ample provision for his old age; or three or four small capitalists might buy one of the large Ontario Wheat farms between them and divide it into small fruit farms.

Strawberries in Ontario are planted in rows about 3 or 4 feet apart. The plants bear in the second year. In the fall they are top-dressed with litter or stable manure. After the fruit is picked in the summer horse hoes are worked up and down the drills, the soil well loosened, and the weeds taken out. This is all the cultivation Strawberries require. The plants bear abundantly for two or three seasons, and should at the end of that period be ploughed down, when a crop of Turnips can be taken off the land without extra manure. The land cannot be too highly manured in which the plants are put. To do the Strawberry culture properly and keep up a rotation of crops a man would require four fields, say of four acres in each. The chief labour connected with Strawberry culture is picking the fruit. This is generally done by children, who pick at 1 cent the quart. The demand for Strawberries is so great that buyers come to the country and give 8 or 9 cents a quart for the fruit on the spot, thus saving the cultivator all trouble of marketing. At the latter price I have known of \$500 worth of Strawberries being sold off one acre of land. The variety of Strawberry most in favour among fruit-growers is Wilson's Albany. The wages of a good man in Ontario accustomed to this work is \$1 per diem if hired by the whole year, or \$1.25 if hired for eight months of the year.—(*Rowan's The Emigrant and Sportsman in Canada.*)

NOTES AND GLEANINGS.

THE retirement from business of Mr. JOHN LEE after his long and honourable career has seemed to some of his friends a fitting opportunity to evince the respect and esteem with which he is regarded, and they propose therefore inviting him to a complimentary dinner to be held at the Horticultural Club, 3 and 4, Adelphi Terrace, on Thursday, February 15th.

At a meeting of FLORISTS at the Horticultural Club on the 31st ult., the final arrangements were made for the Auricular Show to be held at the Crystal Palace on April 24th. The schedule, as drawn up by a special Committee, was adopted with a few slight modifications, which were made to meet to a certain extent the views of the northern growers. The schedule is on a very liberal scale, but the full amount has very nearly been subscribed or promised; a few pounds more would remove all anxiety as to means. The projected show of Carnations and Picotees was approved of, and a Committee, with power to add to their number, was appointed to make the preliminary arrangements. It was the unanimous wish of those present that the show be held at South Kensington. G. F. Wilson, Esq., F.R.H.S., was elected President, and E. S. Dodwell, Esq., Hon. Sec. The sum of £25 was subscribed in the room towards the prize fund.

THE COMMITTEE of the HALLSTON RELIEF FUND have published their report, from which it appears that the amount subscribed has been £779 18s. 7d., of which £699 15s. 8d. was paid to applicants for relief, and the remainder for advertisements, printing, postage, commission to Secretary, and hire of committee rooms.

— Mr. EDWARD BENNETT, Rabley Nurseries, Herts, has been appointed FLORAL DECORATOR AT THE ROYAL AQUARIUM Westminster. Mr. Bennett was formerly gardener at Hatfield, Enville, and Osberton, and has consequently had great experience in ornamental gardening. We understand that some changes in the mode of decoration are to be adopted, and which experience has suggested will be as far as possible suitable to the peculiar nature of the building.

— Mr. DADDS, North Devon Fernery, Ilfracombe, says that he knows more than twenty places within nine miles of the coast of Ilfracombe where the MAIDEN-HAIR FERN grows wild. He has seen at Boscastle and the neighbouring coast more than would load a railway truck. Another correspondent states that he can remember when the Maiden-hair grew among some rocks called the "Giant's Chair," on the Titterstone Clee Hill in Shropshire, but he believes it has all disappeared from there now.

— We are informed that Mr. Charles Turner, The Royal Nurseries, Slough, has purchased by tender the whole of Mr. LAXTON'S STOCK OF ROSES, including both named and unnamed seedlings.

— A MEETING of the Committee of the NATIONAL ROSE SOCIETY was held yesterday at the Horticultural Club, Adelphi Terrace; Hon. and Rev. J. T. Boswell in the chair. The business consisted in the preparation of the schedule and making preliminary arrangements with regard to the Show which is to be held in St. James's Hall in July next.

— In reply to an address lately presented by a distinguished deputation from the ROYAL HORTICULTURAL SOCIETY OF IRELAND the Duke of Marlborough, after expressing his pleasure in receiving the address, remarked that "the pursuit and the science of horticulture and the diffusion of a love for plants and flowers amongst the population are objects which, in my opinion, will tend to embellish a country already highly favoured by nature, to beautify the parks and gardens of the wealthy, and to cheer and render attractive the cottages of the poor." His Grace promised to give whatever aid he could to the Society, and should have pleasure in attending its exhibitions.

— We have received the schedule of prizes offered by the NEWCASTLE, NORTHUMBERLAND, AND DURHAM BOTANICAL AND HORTICULTURAL SOCIETY. This old Society (established in 1824) is unusually vigorous, having as the result of special efforts and energetic management admitted no fewer than 1300 new members during the brief space of two months. The Society now numbers two thousand members, and has a subscription income of upwards of £700. Three exhibitions are to be held during the season—namely, on March 21st and 22nd, July 12th and 13th, and September 12th and 13th; the aggregate value of the prizes offered being £530. About eighty donors have contributed to the special prize fund. The schedule is divided into sixty-seven classes, and the following summary of leading prizes is announced:—Ornamental plants, £125; Table decorations, &c., £90; Ferns, £25; Azaleas, Rhododendrons, and Camellias, £25; Pelargoniums, £38; Roses, £40; Dahlias and Hollyhocks, £30; Fuchsias and Ericas, £25; Liliums and Gladioli, £15; Hyacinths, Tulips, Cyclamens, Primulas, &c., £35; Hardy spring plants, cut flowers, &c., £50; Fruit, £35. The Society is deserving of encouragement and success. The Hon. Secs. are Mr. J. Taylor, Rye Hill, and Mr. J. H. French, South Benwell House; the acting Secretary being Mr. J. A. Stephenson, 1, Queen Street, Newcastle-upon-Tyne.

— A CORRESPONDENT writes to us that a weak solution of carbolic acid (about half a dozen drops to a gallon of water) will DESTROY WORMS AND GRUBS IN FLOWER POTS without injuring the plants. Paraffin (diluted) is also said to have the same effect. We have not tried these remedies, having always found perfectly clear lime and soot water effectual without being injurious.

— We have not to travel far in any direction to perceive mistakes which have been made in planting SHRUBS AND CONIFERS, and especially in small gardens. However small the lawn may be, it seems to have been thought the right place for a Wellingtonia and a Deodar. These deservedly popular trees, with Pinus excelea, P. Douglasii, and others of commanding growth, have been planted "where they could be seen" when young at the fronts of borders and a few feet only from the walk. For a year or two after planting these Conifers look very well in such positions, but eventually they

become too large and have to be mutilated just when arriving at their greatest beauty. Such strong growers should always be planted more or less in the background, even at the risk of veiling their beauty for a year or two, and the advantage of doing so will in the end be decisive and permanent. Very small lawns should be occupied with proportionally small-growing Conifers, and the choice of these is great. Junipers, Cupressus, Thujae, Biotas, Retinosporas, &c., are all suitable for suburban gardens, and are not planted nearly so freely as is desirable in small enclosures. On small lawns small-growing Conifers increase in beauty yearly, but large-growing kinds in such places are incongruous and are not permanently ornamental.

— The representative of a leading firm of seedsmen has sent us the following forcible comment on the letter referring to the PURCHASE AND THE SALE OF SEEDS which appeared on page 84 and headed, "Doing as He Would be Done By:—" "The more one thinks of the present system of the seedsmen's journey sales in the summer—brought home to us by the losses we must sustain this year by the reckless gambling prices at which seeds were sold—the more insane does that system appear. Is there any other trade in trading England where sales are made at a stated price of goods which may perchance never be produced at all? The old system of waiting to see what the harvest would yield was the legitimate one; was fair, honest, and far more profitable to all parties, and more worthy of such a trading country as England."

— The following modes of DESTROYING SCALE AND MEALY BUG which have been found successful by Mr. Kerr at Netherby as recorded in another column, are worthy of being tried by others who are troubled with these destructive insects:—Scale on Peach trees, two wine-glassfuls of paraffin oil to three gallons of water; mix thoroughly and syringe the trees. Mealy bug, two table-spoonfuls of paraffin to one pint of water: apply with a sponge.

— THE "GARDEN ORACLE," by Mr. Shirley Hibberd, for the present year is now published, and contains a great deal of useful information and many illustrations.

— THE Council Meeting of the BATH AND WEST OF ENGLAND SOCIETY was held on January 30th, at the Grand Hotel, Bristol, the Marquis of Lansdowne, president, in the chair. The Finance Committee presented the annual statement, which showed that the pecuniary loss sustained by the Society at the Hereford Meeting (1876) was less than anticipated, being only £160. It was unanimously resolved that "the Mayor and Corporation of Bath having expressed a strong hope that the Patron of the Society, H.R.H. the Prince of Wales, and the Princess of Wales, would honour the city of Bath on the occasion of the hundredth anniversary, and the Council being assured that the visit would be most gratefully appreciated through the entire west of England as well as highly conducive to the interests of the Society, the President be requested to submit an invitation to their Royal Highnesses for any day of the week (Wednesday being the best day), and in any manner which may be most convenient."

— In the course of a lecture delivered on the 2nd inst. by Mr. A. Burrell at the Society of Arts on INDIAN TEA CULTIVATION, it was urged that the soil and climate of India were in every way admirably adapted for the culture of the Tea plant, the produce sent out by the Indian Tea-growers being in no way inferior, and in many instances much superior to the Teas of China. To convey an idea of the steadily increasing consumption of Indian Tea in our own country, it was mentioned that the imports of this article during 1876 had amounted to 27,000,000 lb., or 19 per cent. of the total consumption of the year; while it was anticipated that the imports of the present year would amount to at least 32,000,000 lb., or 25 per cent. of the probable total consumption of the year in the United Kingdom.

DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

KITCHEN GARDEN.

THERE will be plenty of work in this department by-and-by. So far we have done but little, but it was well that a good proportion of the digging and trenching had been done in the autumn. A succession of Asparagus and Seakale must be kept up by introducing a fresh batch of plants fortnightly, the quantity to be regulated by the supply. The heat can be retained in the frames by covering the glass at nights with mats; but Asparagus, unlike Seakale, requires plenty of light in the daytime;

the mats should be removed shortly after daybreak, and not be replaced until nightfall.

A crop of early Potatoes may be raised by planting the sets in frames, if no other conveniences are available. Good loam, to which some leaf soil has been added, is about the best material in which to plant them; over-rich soil has a tendency to produce too much haulm. A few dishes of Potatoes or other vegetables—such as early Peas or Dwarf Kidney Peas, before the earliest out-of-door crops come in, are usually much valued even if a regular supply cannot be maintained. Potatoes and Peas may be had by growing in pots, but it is well to place the pots in a position near the glass and where light and air may be freely admitted. A very high temperature is unsuitable for Peas and Potatoes. Dwarf Kidney Beans will succeed in a Pine house, and they are not so particular about being placed near the glass.

Cauliflower plants in frames or hand-glasses require a little attention. The lights should be quite removed in fine weather, but the plants must be sheltered from pelting rain; indeed, too much wet is injurious. Plants in hand-lights will not require any water during winter. We have now made a sowing of Early London to succeed the autumn-sown plants. The seeds were sown in shallow boxes and placed in a heated frame which has been used for cuttings, for the last three or four weeks. Where a large quantity of plants are required it is better to put 2 or 3 inches of fine soil over the surface of the bed and sow the seeds in that.

A sowing of Broad Beans has been made. The only variety we grow either for late or early crops is a selection of the Windsor. The rows are about 3 feet apart, and about 4 inches are allowed between the Beans in the rows. In heavy soils after so much rain it will, perhaps, be better to keep the seeds out of the ground until it is in a better condition. A good plan, too, is to sow some Beans in shallow boxes, and then place the boxes in any house that is not forced too much. The night temperature should not be more than 65°, and when the Beans are well out of the ground the boxes should be removed to a cooler place and the Beans be gradually hardened, and subsequently be planted in the open ground.

We generally make a sowing of Carrots about the middle of this month on a dry border, and cover the bed with ground vinerias, at the same time Lettuce and Radish seeds are sown. If a gentle hotbed could be made available for this purpose the crop would be ready to gather about ten days earlier. Chives are not grown so much now as they used to be. In small gardens in Scotland a row used generally to find a place; they are a good substitute for spring Onions, and are also used in salads. They are easily propagated by dividing the plants. They are of dwarf habit, and 8 inches between the rows and about 4 inches apart in the rows are suitable distances. A sowing of Round Spinach should also be made now. The soil cannot be too rich. In soil highly manured the leaves grow thick and fleshy, and of a deep rich green. In order to produce Leeks of the largest size and well blanched, a sowing ought to be made as soon as the weather is suitable. The seed may be sown broadcast on a small space of ground, the plants to be transplanted when large enough. We shall immediately make a sowing of Parsnips on rich deeply-trenched ground, but no crude manure should come in contact with the roots near the surface, as this will cause them to become forked. It is a good plan to place the manure in the bottom of the trenches in the autumn.

VINES.

In the earliest house the growths are now making rapid progress, and we have commenced tying them out, arranging them as regularly as possible over the whole surface of the trellis work. The Vines are trained on the short-spur system, the rods being from 2 feet 6 inches to 3 feet apart, and the distance between each spur measures from 15 inches to 2 feet. When Vines are in vigorous health four or five shoots will start from each spur: these are all removed but the two strongest; and when it can be seen on which the best bunches are likely to be, those shoots are tied down a little at a time. If bent too much at once they are liable to snap off close to the old wood. It is better not to remove the second shoot until it is seen that the one to remain is safe. The laterals are stopped two leaves beyond the fruit as soon as the growth is sufficiently developed. We shall in a day or two give a good watering with tepid water, and add some fresh fermenting material to the outside border. A gentle heat is also kept up in the ridge of stable manure inside the house. It is unsafe to put rank manure in the house when the leaves are newly developed unless it is mixed with a large proportion of some that is partially decayed. The temperature at night is raised to 65° after the second watering.

Vines in pots, if it is necessary to have fruit from them in April and May, will now be at that stage which will admit of a high temperature being kept up in the house. Surface-dress the pots with rich compost, and water twice a week with manure water.

Orange trees in the Pine house are heavily loaded with fruit, but only those trees which were in flower after the 1st of March

are in that state, and the fruit is not yet ripe. One tree is now in flower, but unless the weather improves it is doubtful if the blossoms will set well. Plenty of ventilation is necessary during the blossoming period, and the stigmas ought to be dusted with the pollen. Some of the trees seem to do without any season of rest. At present there are fruits nearly ripe, some green and as large as a Potato apple, and a large quantity of blossom on one tree, which tree is in the best possible health, and the ripe fruit very fine indeed. The Orange is a gross feeder, and to obtain fruit of the best quality the plants must be potted in good turfy loam; and when well established regular supplies of manure water are necessary to the perfect development of the fruits.

GREENHOUSE AND CONSERVATORY.

It is now a good time to report show and fancy *Perlargonium* into their blooming pots. We began potting ours on the second day of the present month. After they have been reported they are placed close to the glass, and the growths are tied out to allow more space between them. Sometimes it is necessary to thin out the growths if they are too close to each other. The stage varieties are much more hardy than the fancy section, and they will grow and flower even with indiffererent treatment, but to do them well they should be potted in turfy loam with a fourth part of decayed cow manure, and some silver sand to keep the compost open; a little leaf soil is also an improvement. If the plants are young they do not require so much manure, say one-sixth. It is a great mistake to overpot them: 8-inch pots are large enough for specimens 3 or 4 feet across, and a plant that will produce two dozen trusses will do well in a 6-inch pot. We annually grow a number of plants in 5-inch pots, and they flower profusely. It is better not to water the plants for a few days after repotting them. There are a few early varieties adapted for forcing, but the show sorts succeed best if they are kept in a greenhouse temperature throughout. A few of the best varieties are Ambassador, Diplomatist, Gipsy, George Frederick, Mountaineer, Modesty and Potentate, which are new varieties of last year. Of older sorts the best are Achievement, Admiration, Aristocrat, Blue Boy, Charles Turner, Claribel, Constance, Duchesses of Cambridge, Falcon, Highland Laisie, Iron Duke, Marquis, Mary Hoyle, Prince Leopold, Sultan, Sybil, and Warrior. A few of the best fancy varieties are Countess of Dudley, Duchess of Edinburgh, and Nelly Fortham, which are new sorts. Older varieties are Aome, Anna Page, Atlantic, Cloth of Silver, Eret Lynn, Ellen Beck, Fanny Gair, Godfrey Turner, Henry Baley, Jowan, Jowett, Mrs. Hart, Princess Teck, Roi des Fantaisies, The Shah, Udine, and Vivandiere. The French spotted sorts are preferred by some; they are very pretty, and generally flower freely. A few of the best are Beauty of Oxton, Captain Raikes, Duchess of Edinburgh, Empress, Nabob, Queen Victoria, and Triomphe de St. Mandé.

Cinerarias ought to be in their flowering pots long before this. The plants must be trained as they require it, and those which have filled the pots with roots should be supplied with weak manure water about once or twice a week.

It is now quite time that all the *Chrysanthemum* cuttings were potted. They strike very freely in a gentle hotbed, and as soon as the roots are formed a little more air ought to be admitted, as the plants are apt to draw up weakly in a close atmosphere. Our earliest cuttings have been potted in large pots, and are now in a well-ventilated frame; a house would be better where the frost could easily be kept out. During warm nights the ventilators should not be closed. Success is secured in growing such plants as these without any check, and yet they ought to be freely exposed to the air.

We have repotted plants of different varieties of *Kalosanthes*. This plant does best in rich turfy loam, with leaf soil and sand added to it. Cuttings put in last year in July or August are now in 60-sized pots. They will be potted-on as they require it, and will in the course of the season make very handsome specimens.

All the Dutch bulbs, such as *Hycacinths*, *Tulips*, *Polyanthus*, *Narcissus*, &c., have been removed to the houses where they are intended to flower. Those who have not yet taken the latest-flowering specimens out of the material in which they were plunged during winter ought to do so at once.

We have put a few pots of *Pink Lady* *Blanche* into a house to force. Such common and easy grown plants as *Pinks*, *Mignonette*, &c., are easily brought-on in a little heat, and are very useful for furnishing the front stages.—J. DOUGLAS.

TRADE CATALOGUES RECEIVED.

W. Barron & Sons, 16, Market Street, Nottingham.—*Catalogue of Vegetable and Flower Seeds.*

R. B. Matthews, 65 and 67, Victoria Street, Belfast.—*Cultural Guide, and General Seed Catalogue.*

Stephen Brown, Weston-super-Mare.—*Illustrated Seed Catalogue, with Lists of Dulbs and Roots for Spring Planting.*

Edmondson Brothers, 10, Dame Street, Dublin.—*Spring Catalogue of Vegetable and Flower Seeds, Culinary Roots, Flowering Plants, Implements, &c.*

TO CORRESPONDENTS.

*. All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to un-necessary trouble and expense.

WILD FLOWERS (A Lady).—We are informed by the artist, Mr. W. G. Mitchell, that they will be concluded in thirty more numbers.

RHODODENDRONS AND WIREWORMS (H. B.).—Try oil cake powdered and sprinkled thickly on the roots after removing the soil. It might preserve them. Let us know the result.

HYACINTH (P. F. S.).—The flower-like being compressed by the bases of the leaves is very unusual, but is only one of the unaccountable vagaries incident to plant growth.

CERAPLANTA BRAZILIENSIS (G. H.).—It is a stove evergreen tree, a native of Jamaica, from whence it was introduced in 1739. The tree grows 20 feet high, has orange flowers, and yields the Brazil wood of commerce.

TRAINING CHRYSANTHEMUMS (A Constant Reader).—Let the hoops remain; they will or ought to be completely hidden by the foliage. The stakes should be as thin as possible, consistent with being flamed and stakes a foot to 18 inches long will be little or any thicker than the stem of a tobacco pipe. Stakes double the length may be double that thickness at the bottom, tapering to the top.

PEACH-TREE SPRAY (A. Hopkins).—The decayed places are caused by the unfavourable season, and the young wood being not matured.

PEA (An Old Subscriber).—The description agrees with what is known as the Rose PEA. We will publish your note next week.

SEMI-TRANSPARENT PAPER (An Amateur).—Fasten the paper on the frame, and well-soiled sheet of glass.

STOVE CLEMATIS (A Learner).—As you have Stephanotis floribunda, and need two more, obtain *Clematidum Balfourii* and *Ipomoea Horsfallii*.

GROWING ASTERS IN POTS (P. F. S.).—Sow the seed during March or early April (as you require the plants to bloom early or late) in pans, placing in gentle heat as that of a hotbed. When the plants appear keep them near the glass, and well ventilated to prevent drawing. Pot them singly in 3-inch pots, watering as usual, and keeping rather close and shaded until well established. After this admit air freely, the main points being to keep them slowly growing, and not allowing them to become pot-bound before shifting into larger pots. If sown in March the plants will be strong and well hardened off by the beginning of May. An 8-inch pot will meet the requirements of single plants, a 9-inch tub, and a 10-inch or 11-inch will answer for five plants. The soil may be composed of three parts turfy loam and a third of thoroughly decayed manure or leaf soil. The plants should be potted rather firmly in well-drained pots, and have a light and open situation if continued under glass, which we do not advise, but would assign them a situation on ashes. After the plants fill the pots with roots, water them with weak liquid manure. If sown during early April the plants will require their blooming pots by the close of May or early in June.

CONSERVATORY WITH EAST ASPECT (W. M.).—Your house being cold will not answer for plants requiring protection from frost, as *Pelargoniums*, *Fuchsias*, &c.; nor for a Vine, which would not answer in an unheated house in winter. We should advise you to decide between Ferns and Roses. If the first, we would have the Ferns planted out, forming rockwork for them, and selecting the better kinds of hardy Ferns. If Roses are determined upon, we should advise for planting them out in borders within the house, though for the roof the roots may be outside, the stems being introduced through the wall in the interior, and the plants being taken up by Roses trained to pillars as pyramids, and the back trellised for climbing Roses. The kinds we should choose for this purpose would be Tea-scented. Should you decide to heat the house so as to exclude frost, you would be enabled to have a greater variety of plants; in fact, most greenhouse plants would thrive in it, and those would afford you greater satisfaction that could be had from an unheated house devoted to but one class of plants.

AN AMATEUR'S VINEY (Sir Astley).—Do not attempt training up climbing Roses in a viney, or both Vines and Roses will fail. Devote the whole of the roof to the Vines, and grow your Roses in pots, introducing a few in succession into your front bed, where you will also and Tomatoes answer well, and you will not be obliged to have the house being taken up by Roses, they should be grown in pots. You may also grow excellent crops of Cucumbers in pots planted in the bed. If you attempt this, do not fail to give them an abundant supply of liquid manure, or the fruit will prove small and very tipped.

VEGETABLES (W. P.).—As your soil produces good Turnip Radishes, but not the long varieties, we recommend you to try putting some well-decayed manure at the bottom of each trench when the ground is dug. The roots will probably descend straight to it.

AZALEAS LOVING FOLIAGE (W. Hamilton).—Carelessness in watering and the attacks of insects are generally the causes of the bareness of which you complain in your plants. Let the plants be closely examined, and if any signs of insects will upon the leaves, they should be rubbed with a weak soap and tobacco water, repeating the operation on alternate days for a week. If the pots are small in proportion to the size of the plants and are crowded with roots report at once in light fibrous soil with plenty of white gritty sand mixed with it (see part last to three parts part), take special care that the drainage be thorough, the trees to become very rammed in, and use pots of 11 to 2 inches more in diameter than the old pots; take the plants from the potting bench to a somewhat shaded position in the hot-house, use the syringe freely, but apply water to the roots sparingly till the new growth is pushing freely; after they have finished growing place them in a sunny position to ripen the new growth. When the flower buds are so far developed that you can feel them remove the plants to a cooler temperature, and let them have plenty of fresh air. The most important points in the culture of Azaleas are—the watering, cleanliness of the foliage, an early and well-thought about attention to the insects, which we have described, and abundance of air and light after the growth is matured.

INARCHING GRAPE VINES (Constant Reader).—You may inarch the Vines as you propose, but our experience tells us that what succeeds well in one instance will not do in another. Black Hamburgh is a good stock for

Blackland Sweetwater. Lady Downe's does best on its own roots. We should like to know the result of your inarching Mill Hill Hamburgh on Chasseles Masque.

BEST BRASSERIES (J.).—Yellow Antwerp, Fostell, Prince of Wales, and Red Antwerp. *Choccoleries*: Red Warrington, Red Champagne, Early Sulphur, Yellow Champagne, Rumbullion, and Green Gascoigne. *Currants*: Black Naples, Black Castle, and White Dutch. Any respectable tradesman can supply you.

HEATING LEAN-TO HOUSE (E. D. L.).—Two rows of 4-inch pipes might heat a house 9 feet wide by 6 feet 6 inches at back; but to keep up 60° in all weathers you ought to put in three rows.

MARKING A HOTBED (W. Fitzpatrick).—See reply to "E. G. M." To raise an early *Yarrow* the position you mention a very slight hotbed will suffice say from 2 to 3 feet in height, well tramped, and covered with 3 or 4 inches of rich sandy soil kept on the bed by strips of board not much wider than the soil is deep. It is, of course, best to cover the soil with glass sashes, falling, which wooden screens, feeling stretched on frames, or, in fact, anything which will throw off the rain and exclude frost will answer admirably. Sow the seed during March, but before doing so the hotbed should have been made about a week in order to avoid rack burnish heat. Cover the seed thinly with soil, water when necessary, and throw off the covering upon every favourable occasion, in order to prevent the seedlings from becoming drawn up and weakened.

SEEDLING AUCUBAS (J.).—There is no determining the sex by the variegation or serration of the leaves. The coarsely serrated-leaved seedlings we think are mostly female, though in the smooth-leaved plants we apprehend you will have some female, but taking both together we anticipate the sexes will be about equally divided.

GROWING DANIELS, &c. IN POTS (A Great Lover of Flowers).—Dahlias may be put in pots, and, indeed, every description of plant. The best kinds for pot culture are the dwarf bedding varieties, as Bob Ridley, Leah, Baring Sun, Scarlet Gem, Down Queen, Cloth of Gold, Little Wonder, and Dwarf Queen. Of the Dwarf varieties—Glow-worm, Northern Light, &c. Webb, Sacramento, White Ash, and Little Love are good. They must not be allowed to become pot-bound, but be shifted into larger pots as required, giving the final shift at the end of May or early in June. Twelve or 18-inch pots are necessary. If you grow the Show and Fancy varieties they will require 15-inch pots. Hollyhocks must not be allowed to become pot-bound, and the plants may be put in potting pots at the end of April or early May. Plants with one stem may be grown in 13-inch, or with two or three stems in 15-inch pots. Antirrhinums do well in pots, requiring 8-inch pots, into which they must be placed in March or early April. *Chrysanthemums* should be struck from cuttings in March in gentle heat, and the plants well rooted, and then placed in cold frames in a cold frame until April or May, then placing on sashes in an open situation outdoors, shifting into larger-sized pots as required, keeping from becoming pot-bound, and moving into the blooming pots early in June, when the plants may again be stopped, affording 9-inch pots for Tomatoes, and 10 or 11-inch for the large-flowered. *Caryophyllus* and *Gloxias* cannot be layered in pots unless unnecessarily large. Layer from plants planted-out. Pentstemons may be grown well in 8 or 9-inch pots. Any very vigorous plants may have 10-inch pots. All should have an open yet sheltered situation, be well watered, and with liquid manure as usual, and the plants should be kept in the house until the flowers. We know of no means of distinguishing in the young state single from double-flowering plants of *Margiolds*. The strain is a bad one to have so many single.

PLANTING RIBBON BORDER (Idem).—Commencing at the back of the border—*Geranium*, *Ageratum*, *Tigetes* signata pinnata, and Best, and we would advise an oblong plant of *Pyrethrum Golden Feather*, or a dwarf silver-leaved *Cerastium tomentosum*.

PYRETHRUM (H. T.).—You had better write to Messrs. Carter for the information you seek. Mention the size of the ground and they will readily answer.

TWIN APPLES (G. B. C. Woburn, Beds.).—We have never seen this twin Apple before. The only variety possessing this character is the Cleator Apple, and we should like to know if you have seen us. We should like to know its history if you can supply it to us. The pale one is Cockpit, and the coloured one Moss's Incomparable.

DUNG HOTBED MAKING (R. G. M.).—We will commence with the dung fresh at the stable door. The first thing is to throw it into a close body to "sweat." Shake it over loosely and reject a portion of the mere droppings, for these take the most putrefying, and, moreover, expel a great deal of the material thus thrown together will in a week or so become exceedingly hot, and must then be turned completely inside out, and in so doing every lock or patch which adheres together must be divided. Water now regularly as the work proceeds, rendering every portion equally moist. After the mass has become so hot as to be added to the mass they may be so at the last turning but one. The heap ought now to be "sweet," a beautiful drawn from the very interior and applied to the nostrils will not only be devoid of impure smell, but actually possess a somewhat agreeable scent, similar to the smell of Mushrooms. Select spots perfectly dry beneath, or rendered so, exposed to a whole day's sun; but the more it is sheltered sideways the better, as starling winds, by suddenly lowering the temperature, cause a great waste of material as well as of labour. Some portable screens, therefore, are useful things for early work. The ground surface should be newly level. It is well also to fill most of the interior of the bed, after building it, half a yard in height, with any half-decayed materials, such as half-worn linings, fresh leaves, &c. This will in general secure it from the danger of burning, whilst it will also add to the permanency of the bed, for the Cucumbers roots will descend, and thus secure an indefinite amount of food during the winter. The bed should be secured as built let some litters mature be placed round the sides in order to prevent the wind searching it. As soon as the heat is well up, or in about four days from the building of it, the whole bed should have a thorough watering, and now water as usual, but do not close it up, and do not use a second and lighter watering may be applied, and now it will be ready for the hills of soil. Not knowing on what system you intend to train your Vines we cannot advise how to prune them. Buy our Vine Manual.

NAME OF FRUIT (*W. H. A.*)—Bezi Vast.

NAMES OF PLANTS (*Mary*).—*Sparmannia africana*. It is a shrub, native of the Cape of Good Hope. It is a greenhouse evergreen, requiring common garden soil with a little peat added, and is propagated by cuttings of the young shoots during April. (*Juno*).—*Stachys lanata*. (*F. Walker*).—We cannot name any plant from a dead flower. (*F. M. H.*).—We cannot name your *Dracena* from the leaf sent. (*F. H. Cumming*).—*Heliconia foetida*, (*Gardener*).—*Pteris orifolia var. cristata*. (*Roh.*).—The blue flower is *Agathis cespensis*. The other is insufficient for determination.

POULTRY, BEE, AND PIGEON CHRONICLE.

POULTRY AND BIRD NEWS.

We observe a show is advertised for Banbury. We are glad of it, as that part of the world is but poorly off for shows. With the influential names of the Judge and Secretary it should be well patronised.

This being the hundredth anniversary of the Bath and West of England Agricultural Society, the Committee have wisely determined to return to their birthplace. We hear the preparations are all in full train for the meeting. The Royal Counties will meet this year at Southampton, so we shall hope to find our Channel Island friends well to the front.

The malicious injuries wrought upon prize poultry have been very great of late. We know fully well that sometimes at a show in punning, basketing, or cleaning out, a wild bird will break or drop a feather or two; but it is remarkable that of late so many of these feathers have been plucked which have materially injured a bird's winning. For instance: Mr. P. Haines had a Light Brahma hen injured in her tail; Mr. Dean had his Golden-spangled Hamburg treated the same; and the first-prize Dorkings came back, too, from Kingston like little Bo-Peep's sheep—tailless; and now we hear that Mr. Norwood has his cup Black Poland cock come home minus a sickle.

The Bristol Show has again been a failure; nearly £100 to the bad, and Mr. Cambridge, on whom the loss alone falls, wishes all prize-winners to take their prize money minus 25 per cent. As this appeal comes round with a most gentlemanly and straightforward circular, we hope all who can afford to do so will take their three-fourths. Still Mr. Cambridge had no right to issue single-handed his schedule unless he was prepared in the case of loss, which he must have anticipated, to defray all expenses.

Eggs seem unusually plenteous this season, but broody hens are as scarce as ever. We hear of birds being sent for from far distant places to sit upon the spoiling eggs. It does seem a pity that no incubator has been manufactured to come within the price and accommodation of all. Some people we hear systematically make year by year a good trade from selling "a broody hen, nest, egg, and all" for 5s.

We regret very much to have to announce the death of another of our poultry friends. Mr. Ridpath died last week at his residence, Withington, Manchester. Although not so well known, perhaps, as many other fanciers, still all who knew him bear record of his kindness and perseverance in the good cause.

Fanciers of the real Indian Game, not those of the Malayan cross, who are really anxious to establish the breed in England and are willing to help on the work, will find a very ardent coadjutor in Mr. J. King, II, St. Aldate's, Oxford, who, being the Honorary Secretary of the Exhibition there, is always willing to advance the interests of uncultivated breeds. Those not feeling inclined to subscribe can at least guarantee entries provided there is a class.—W.

OUR DUTY TO OUR FOUR-FOOTED AND FEATHERED NEIGHBOURS.—No. 3.

BOY-CRUELTY is not the only cruelty which animals have reason to dread. In a sneaking underhanded way there is still much man-crueity in England. I heard of a man confessing to have trained his terrier pup to kill rats by first catching a rat and extracting his teeth, and then letting the puppy go at it. This was said not in any way of boast, but as a recommendation to a purchaser of the dog. The dog was bought and the man, a travelling hawkster, went on his way and escaped, I regret, prosecution. Then there is the man-crueity of the cock-fighting snook, the loathsome creature. There is also too much cruelty or unnecessary severeness in the breaking-in of horses. There is too great roughness, and beating and kicking too, of horses by stablemen, especially when the latter are the worse for beer. A dog will not, such is his dislike of the smell of wine and liquor, go into places where such things can be smelt. You cannot induce a dog to smelt a wineglass that has had wine in it. How much horses must dislike the smell of stale beer, as they have to connect heavy breath with stableman cruelty! Then there is the bearing-rein cruelty. The docking and cropping of horses has become unfashionable, and was given up because of that; not, I

fear, because of its cruelty. In olden days I have known a horse twice docked in order to shorten the tail to the taste, or want of taste, of the owner. Some of my readers may not know what docking is, but I have seen it done when a little boy I can tell them. See—blacksmith's shop. Blacksmith a huge, fat, scorbuto-faced man, always in liquor after dinner. He began with bitters before breakfast, glasses round at his favourite pot-house at eleven, a heavy soak with his dinner, and afterwards more and more. He, unlike Longfellow's blacksmith, never

"Went on Sundays to the church
And sat among his boys;"

he never

"Heard the parson pray and preach,"

but his shop was known to the ear before the eye saw it, from the loud rattle of some poor apprentice, or it might be some fidgeting horse sent to be shod. Well, the poor horse is brought to be docked. The hairs of the tail held back, the real tail laid bare, then the big shears descend, a piece is cut off, and instantly a red-hot iron is applied to the bleeding sore. Oh, the agony to the poor animal! and all done for no useful purpose, only for fashion sake. Plunging, writhing with pain, the poor horse is taken home. The result, instead of a tail to lash off the flies in summer, he had what looked like the inverted head of a tobacco pipe, of no manner of use whatever. Am I told all this is a thing of the past? Granted; but fashion not seldom takes a backward turn, and old fashions become new.

At any rate, the Rabbit trap of the gamekeeper is no thing of the past. Going his rounds the keeper sets his traps. He may not again go the same round for two days. Meanwhile a Rabbit sporting in the twilight is caught by the leg. The Rabbit is a very timid creature, and timid creatures are always very sensitive of pain. The poor Rabbit tears at the trap, deeper go its teeth, and they meet at the bone. Hour after hour, and perhaps many hours of agony follow. At every noise those fine trumpet-like ears revolve on their pivots—those ears made to catch every sound, and made to revolve so as to catch it more readily. At length the keeper arrives after many an hour, the Rabbit is dragged out of the trap, and then at last, at long last, its misery is over. In all the above cases there is cruelty. As to Rabbits, land in England has become so valuable that, except in that peculiar land unfit for anything save a warren, Rabbits perhaps ought not to be allowed to live, but they should be killed with as little pain as possible. Our duty to animals and birds is not hard to learn; we must not be overwhelmed by them, but they must be kept in due proportion, a proper equilibrium being maintained.

In the rural districts of France a proclamation has been posted on the signboards and at the corners of the roads headed with the arresting title, "Ministry of Agriculture." This placard warns the French farmer in brief but admirably chosen language to the following effect:—"Hedgehog: lives on mice, small rodents, slugs, and grubs, all animals hurtful to agriculture. Do not kill the hedgehog. Toad: farm assistant, destroys from twenty to thirty insects an hour. Do not kill the toad. Mole: is continually destroying grubs, larvae, palmerworms, and insects injurious to agriculture. No trace of vegetation is ever found in its stomach. Does more good than harm. Do not kill the mole. May bug and its larva or grub: mortal enemy of agriculture; lays from seventy to eighty eggs. Kill the May bug."

In regard to birds there has been much ignorance in the lower classes, particularly gamekeepers. As a rough rule it may be well to remember that though some hard-billed birds may do some harm, soft-billed birds, the eaters of insects, can only do good. In parts of Scotland where the gamekeepers have of late years had orders to destroy all hawks, owls, and other birds of prey, on the ground that they kill the young game, the result has been that field mice have increased to such an extent as seriously to imperil the annual crop, and where weasels have been all shot rats have increased disastrously. All should be kept in due proportion, and then a proper balance will be maintained. The killing of every hawk is a great mistake, the kestrel, for instance, feeding only on mice, and no better friend exists than the owl.

There is another animal that I plead for, the graceful squirrel, Nature's better Blondin, because he fearlessly walks the slack rope of the bending tree branches, while Blondin only waded the tight rope when high in air. We have all too many wild animals in England, let us be careful of the few we have left. The squirrel is the very personification of graceful agility; every movement is graceful, and his activity wonderful. On the ground one sees his full, bold, liquid eyes; ascending a tree pursued by a cat we see the little creature's activity in danger. Once safe how he turns, stamps his foot, and barks his defiance; and when going from tree to tree across the most slender branches we see the perfection of self-reliance. Then he always abounds when his natural food abounds—the beech nut; those he loves best and lives on. Sometimes gardeners complain of his depredations, but usually I think the squirrel bears the blame when he ought not. Just as in the house, it is "that cat" when a dish is broken or a more than usually toothsome viand

is missing, so when an apricot is gone here and there, or filberts by the handful are missing, it is always "those squirrels." Is it not sometimes "that gardening boy," who, although he is perhaps high up in his teens, has his school-boy love of fruit and nuts still in him? I seldom believe charges against animals, for it is so easy to blame them; poor dumb beasts, they cannot defend themselves. For "that cat" and "those squirrels" read "servants." One mischievous squirrel certainly do, and that is they bite off the early spring shoots from some trees, notably fir trees, and in a young plantation of these they must be destroyed, but in other situations they may be encouraged, for they will only be numerous when the beech mast is plentiful. I carry not the heart of that man who can enjoy shooting a squirrel. If the deed must be done it must, but many a man I believe commissioned to kill squirrels regrets that he has to do it—almost wishes his gun may not point true for once, and if the little graceful creature falls, says pitifully, "Poor pretty little thing!" I know of no animal that resembles the squirrel; it stands alone as what I have called it, "Nature's better Blondin."—WILTSHIRE RECTOR.

PREPARING POULTRY FOR MARKET.

POULTRY should not only be fat when killed, but should be properly dressed and put up for the market. Poor goods may not sell because they are presented in an attractive form, but the best will not bring good prices unless they attract by their appearance. After the fowls are killed comes the most exacting part of the work of preparation. The skin must not be broken, it must not be parboiled, pin feathers must not be left in, nor the down stand out like the first whirl furze on a boy's face. To prevent these unsightly and repulsive appearances follow a few simple and natural directions. Pluck the fowl while the animal heat still remains. Do not kill at a time more than you have facilities for immediately dressing. The use of hot water is certainly essential, but do not have it hotter than is absolutely necessary in order to start the feathers. Pick out all the pin feathers, using tweezers if necessary, but do not tear the skin. Singe the plucked fowl over a gas jet or the flame of a kerosene lamp; in the latter case it is sufficient to hold the fowl over the glass chimney of an ordinary kerosene lamp, turning the fowl rapidly. The work may be done in a few seconds. Some prefer a handful of feathers or a few scraps of paper kindled to a quick blaze to the fireplace or stove.

In some markets poultry is sent with crop and intestines undisturbed, probably as much because it is thought the fowls look fairer and plumper as for any hope of gain from extra weight. It is preferable on some accounts to draw the fowls. The French market women draw their poultry, carefully wipe out the cavities, and stuff with a bunch of clean unsized paper—ordinary straw or Manila paper, and their poultry is delightfully sweet and attractive.

Poultry should not be packed for transportation until entirely cold. Then it should be laid in clean straw, breast down, keeping the wings and legs close to the body. See that there is no discoloration of blood on the skin. If the heads are removed pull up the skin of the neck, and tie it over the severed portion with a bit of strong thread or twine. Never cut off the spurs of old hens or cocks with the idea of passing them off for young chickens. Purchasers are generally older than the most ancient specimens of your poultry-yard; or if perchance the customer is green, that is no excuse for dishonesty.—(*Canadian Poultry Journal*.)

CRYSTAL PALACE BIRD SHOW.—The fourteenth annual Exhibition of Cage Birds is fixed for the 17th to the 22nd of February inclusive, and promises to be more attractive than ever. For foreign birds especially the amount of prize money has been doubled in most of the classes, and the prizes offered throughout the schedule no doubt will bring forth large entries. There are no less than eighty-six classes for birds, a class for cages, another for the best collection of nest boxes for cage and wild birds. Class 90 provides space for authors, publishers, and booksellers who may think well to send books relating to cage birds. This we look upon as a novelty in connection with bird shows. The entries are to close February 2nd, and post entries February 10th.

THE BEES IN JANUARY.

As we all know the winter has been with us exceedingly mild it is natural to suppose that the bees may have declined to an abnormal condition, and it will be well, when an unusually warm day occurs to investigate the state of the hives and their inhabitants. On January 3rd the sun shone bright; the bees were full of life and activity, so I made an examination of my colonies. The first frightened me—to my surprise not an ounce of honey was in the hive. In fear and trembling I opened the remainder one after another, gaining spirits as I proceeded, for the first was the worst. Several others were poverty-stricken, but none

so bad as that. I saw the queens of all the hives, some of which had babies in their cradles; so into a stewpan went 8 lbs. of lost sugar, which, being boiled into barley-sugar and broken up, was soon distributed among the paupers, as well as some full combs of honey-gleaned from richer colonies which could spare it.

Now it is not easy to persuade bees to take food into their hives in winter, and my barley-sugar in No. 1 colony was merely sniffed at; but a half-full honeycomb put right into the brood nest soon brought the bees' pluck up, and a week afterwards I found the barley-sugar gradually disappearing, and still a week later found breeding in progress, one fed hive having a patch of sealed brood as big as the palm of my hand. So far so good; and every week of mild weather following gives a better chance of surviving until the spring, for in another month, unless very cold, breeding will actively commence and food will readily be taken from the bottle, when all danger will be over. If January had been as we might have expected it, very cold, one at least of my colonies would have perished, which of course should have fairly been set down to bad management; but my investigation seemed to tell me that the bees had consumed more food than is usual in winter, by reason doubtless of their greater activity, the semi-dormant state in very cold weather not having occurred.

I cannot help rejoicing that I do not patronise straw skeps, for in that case no such examination and relief as I made would have been possible. But

"'Tis with our opinions as our watches—none
Go just alike, but each believes his own."

I have no hives to sell, and should prefer every bee-keeper would please himself and let others do the same.—JOHN HUNTER, *Eaton Rise, Ealing.*

HIVES AND LOCALITIES.

YOUR correspondent Mr. Pettigrew, in a communication under the above heading, gives in his adhesion to the theoretic views enunciated by Mr. Lowe in an article entitled "The Battle of the Hives." Mr. Pettigrew's change of front is indeed thorough. Since he came amongst us we have heard much of the great harvests of honey reaped in and through his large straw hives. To prop up Mr. Lowe's position all this teaching is thrown overboard; for does not Mr. Pettigrew now unhesitatingly proclaim it matters not of what material and how constructed hives are to expect any increase of the honied store? Even his large pot straw (the Crystal Palace bar-farms prize) and the Stewarton all are reduced to the common level of "the boxes from a grocer's shop." Mr. Lowe thought rather cautiously "that the kind of hive cannot have much or any influence on the amount of store collected by the bees;" but Mr. Pettigrew, anxious to outvie his leader, loudly disclaims thrice over—"No, nothing" of gain.

How evanescent are the teachings of theory when brought to the test of experience. I have already shown Mr. Lowe from my own apiary the honey results from one hive during all the years of its establishment to be simply *nil*, the untoward state of matters being solely attributable to its "form, material, and construction;" and in like manner I can assure Mr. Pettigrew that the superior results obtained from one hive and system of bee management over another is by no means an "isolated," but a most common experience. This I can illustrate over and over again. Take the case of the ten supers obtained from one colony in 1868. When I spread them out for the inspection of the most extensive and experienced straw-hiveler in our neighbourhood, he had the candour as well as the frankness to tell me that from that one colony I had reaped that season more honey than he from his entire apiary. To be sure I had one advantage over him in possessing the Italian bee, in addition to the improved hive; still this same stock yielded a greater crop than did all the straw skeps in my own apiary put together, although similarly peopled. To go no farther back than last year: while "the best hive," my strongest Stewarton (No. 7), yielded nine supers in all; No. 12, an eked straw skep, gave neither swarm nor honey, refusing to ascend into the glass. No. 9, another eked straw, gave one artificial swarm and stored 13 lb., sufficient to seal-out and make presentable to send to a friend the Abingdon glass, wrought on No. 11 the competitive straw of 1875. No. 7 gave two swarms and reaped all supers, so that against the nine supers from one Stewarton I had last season 13 lb. of honey and three swarms from my three straw stocks; but fortunately they were equally with the Stewarton, a rather unusual circumstance, independent of all feeding.

Mr. Pettigrew states that Mr. Phillips of Hitchin has told me he reaped last season the harvest of 154 lbs. from a straw skep, and adds—"In Lanarkshire and other parts of Scotland swarms in straw hives, and the stocks that yielded them in 1875, rose to 70 lbs. or thereabouts, whereas the straw hive of your Kenfrewshire correspondent, which never swarmed at all, was at starvation point after the super of 20 lbs. was removed." And may I ask, What does this go to prove? Simply what a land of Canaan the counties of Hertford and Lanark must be to the comparative desert wilderness in which our camp is pitched. The strict

inquiries after the health of our competitive straw has amused us not a little, for was it not the premier straw hive of our apiary? and were we not a little proud of the heaviest and best glass of honey we ever harvested which it yielded, when our other straws, equally healthy, gave nothing, and less than nothing? they and their swarms requiring to be heavily fed early in the season, while with our neighbours, where this had been neglected, the bees were dead and dying all round. Such a weight as 70 lbs. with a single swarm in our poor district we have never seen, clearly demonstrating the necessity we have already pointed out for comparison being drawn on a common scale. It also proves the thorough efficiency of the Stewarton implement we possess for our miserably watery west coast. We cannot here afford to subdivide our forces; we must combine them to improve each blink of sunshine, and when favoured with a genial spell is it not surprising the feats their conjoined numbers can perform? which, according to Mr. Lowe, even "staggered" the faith of our friend Mr. Pettigrew in the straw, which the former gentleman's plausible theory has now altogether overturned.

Mr. Pettigrew descants "on the condensation of moisture on the inner side of wooden hives. . . . and hopes that a cheap and satisfactory mode of ventilating wooden hives may soon be discovered and made widely known." He says, "The quilt, an American idea, has been tried in this country without success, so far as I know." This evil is unknown in our apiary, either in hives of wood or straw. Your correspondent, possibly being in ignorance of what our old job testifies, that sixteen years ago, when this periodical led the van of apianism thought, that the present writer proved how that by the employment of India or Cuba matting, a hive—not of wood only, but of glass—was so thoroughly ventilated as to withstand a frost within the hive on the memorable morning of the 24th of December, 1860, and came through dry and in fine order; and how the first authority on the American continent, Rev. L. L. Langstroth, subsequently approved and recommended the same material as being thoroughly efficient for such a purpose.

It may interest Mr. Pettigrew's Cambridgeshire correspondent to know that my favourite hive, the Stewarton, so far from being lauded, was not so much as mentioned in any work I could procure on my beginning bee-keeping, its fame being then merely local; and it has been brought into notice principally through the present writer's pen in these pages and elsewhere when an amateur's recommendation to his fellows, who never had the smallest personal interest in any hive whatever. The superiority of its results, in quantity as well in quality, were seen to advantage on the first and second prize displays at the Great Exhibition of the British Bee-keepers' Association at the Crystal Palace, when the leading journal pronounced "that the Scotch honey eclipsed everything."

How often do we find parties, possibly denized in the environs of towns, lay the blame of their failure in bee-keeping on their locality, when a glance at their hives would lead to the supposition that their intention was to cramp rather than stimulate the industry of their bees. Some years ago a Greenock acquaintance, Mr. B.—, sought my opinion as to the feasibility of his setting up a hive of bees in the centre of his villa garden situated at the top of a populous street, which, with his little greenhouses to one side, he thought would then be complete. Were the bees to turn out self-supporting in summer he would not grudge as much sugar as would feed them over the winter, and then in a special good year, could he but get a bit of honeycomb for his table, what a treat it would be! After discussing the distance of surrounding foraging grounds I thought it worth a trial. His idea of a hive was one in which he could see the bees at work, in which they could be prevented from swarming—for his being absent in town all day the swarms would be lost, but he could devote time morning and evening to looking after them. I recommended the Stewarton hive, and gave him the address of a maker and of a cottager in our parish who supplied a prime swarm. The stock was set up in an ornamental octagon cover, back portion hinged; he wrought under my directions, and it proved a much greater success than either of us could have anticipated, even to the extent of his harvesting one good season six octagon supers. In course of time the first octagon stock became flanked by one on either side, and he not only supplied his own table to satiety, sweetened all his friends', but actually sold honeycomb. His great success ultimately proved his ruin. Gentlemen who kept bees more in the country twitted their gardeners as to how they could not supply their tables with equally beautiful comb from their straw skeps. Some maliciously-disposed person during the night entered my friend's garden, and robbed and utterly wrecked all his colonies.

I was recently introduced to an apianist in the same town; among other things the peculiarities of last season were discussed, and in such a locality as his bees could not be expected to do much. What hive did he find field meet? The Stewarton to be sure. What had been considered his "best" hive came next. Such a year three full-sized supers, instanced Mr. B.—'s six supers same year. He had heard of that case, but there was

something mysterious about it he could not comprehend, for were not their gardens close to each other? The mystery was soon solved. What depth of box do you use? 9 inches was the reply. How many of these constitute your set followed? Of course, one; to which I rejoined, "Your workshop of but one 9-inch box gave elbow-room to a given number of willing hands; Mr. B.—'s, at 18 inches of breeding space, to double your number. Your force turned out three, all you could expect; his, six full-sized supers." Such is the beautiful exactness with which honied results are proportioned to the construction of hives placed on a common field.—A RENFREWISH BEE-KEEPER.

OUR LETTER BOX.

ELEPHANTIASIS IN FOWLS (Rooster).—The first appearance of elephantiasis (St. Anthony's fire), is the formation of a sort of white crust at the edge of each scale of the leg. At this stage we have known it cured by frequent administration of sweet oil by means of a feather, or by constant application of ointment. If afterwards increases, penetrates beneath the scale and raises it, filling the space with white crust. This increases till the legs even of a young fowl resemble the upper shell of a coarse oyster. We know no cure for it in this state. It, nevertheless, is not a disease from which fowls suffer either pain or inconvenience. We have only known it among fowls in confinement. In a large pen where some have had it, we have never known it affect all the birds. As a rule it attacks adults, but we have known chickens catch it. The ground oats can be made only with stones dressed on purpose. Ordinary grinding is worse than useless.

EDINBURGH COLUMBARIAN SOCIETY'S EXHIBITION.—Mrs. Iadd writes to say that some of her prize Pigeons have been injured and lost during their return homewards. The baskets to pass through so many hands between Edinburgh and Cairn that it will be difficult to detect the culprits.

REMARKS.

- 31st.—Fine morning, solar halo between 8 and 9 A.M.; fine till the evening, when the rain and the evening was again rain.
 1st.—Dull and damp all day, but scarce any rain.
 2nd.—Neither sun nor rain all day; stars very bright at night.
 3rd.—White frost in morning, fine forenoon, rather less bright in the afternoon; fine evening, and starlight night.
 4th.—White frost followed by a fine bright day, brilliant sunset, and starlight night.
 5th.—Slight white frost, fine morning and fair till 5 P.M., when it began to rain and the evening was showery.
 6th.—A damp, dull, disagreeable day; rain at intervals during the day, and more heavy at night.
 Very mild, ad., excepting on the 31st, somewhat drier than for some weeks past.—G. J. SYMONS.

COVENT GARDEN MARKET.—FEBRUARY 7.

We have no alteration to report from last week.

From observations taken near London during forty-three years, the average day temperature of the week is 45.6°; and its night temperature 30.8°.

WHEN TO GIVE AIR, AND WHY.

WHO dares say anything against the time-honoured "chink of air" insisted on by so many first-rate gardeners? It would seem at first sight to be almost madness to do so, and at the same time to own that probably the greatest number of successes are to be found at present where the said chink is held in great veneration. Nevertheless I say unhesitatingly that the necessity for the chink of air on forcing houses night and day in winter is only an imaginary one, and to keep it on regularly is extravagance.

As a general rule, houses which have their roofs constructed principally of glass do not require opening at all so long as the atmospheric temperature has to be assisted by fire heat. Those who recommend a constant chink of air imagine it is necessary for the sake of supplying the plants with fresh air, and this idea when looked at in the right light is altogether an absurdity, and will only become reasonable when our glass fittings are made air-proof. Imagine a forcing house at 70° while the outside temperature is 30°! A good arithmetician could tell you how long it would take, if shut as closely as possible, to change its air entirely. I have not the least idea of the length of time it would take, but certainly not many hours, and of course with a greater difference between the two temperatures the more rapid would be the change; consequently the less need would there be to open the ventilators. Anyone who will look at the matter for a moment will see that it takes at least four times the amount of hot-water pipes to heat a forcing house that it would to heat a dwelling house to the same temperature; and again, a forcing house well covered or double-glazed will take a third less fuel than it otherwise would to keep it up to the required temperature. All this goes to prove that in an ordinary forcing house when the outside temperature is low the change of air is sufficiently rapid for the good of the plants.

Not only is fuel wasted by giving air when the plants have already a sufficiency of it, but the tissues of the plants are dried up, and they become an easier prey to insects. I know there are people, and good gardeners amongst them, who will scarcely credit that it is possible to force Kidney Beans, Strawberries, &c., in winter without red spider. Let all such banish their old notions about giving the constant chink of air and high artificial temperatures, and they will find that it is easier to go on without this and other pests than it was with them. By-the-by, I find high night temperatures, the venerable chink of air, and a plague of insects keep company very constantly. I have often been at a loss to understand how so many of our good gardeners will insist on a high night temperature and declare that their plants will not exist under the conditions, and often name, say, for instance, 55° for Cucumbers and Vines in full growth. Now I think the chink of air must have something to do with it. We know that we may feel quite comfortable as to warmth

at one time with the thermometer at 40°, but an east or north-east wind will speedily deprive us of that comfort, though the thermometer may declare the temperature to be 55°.

When and why is it necessary to open the ventilators?

1stly, When there is not sufficient difference between internal and external temperatures to cause circulation and consequent renewal of air.

2ndly, When blossoms are expanded which require fertilisation, a more rapid circulation than usual is necessary to dry and distribute the pollen.

3rdly, When there is a likelihood of the temperature rising too high or too rapidly from natural causes (not after it has risen, mind); the rising must be anticipated).

A rapid rise of temperature does not harm many hot-house plants, excepting they are bearing fruit or flowers, when, owing to the fruit and flowers not being warmed so quickly as the surrounding air, moisture immediately condenses on them, and is very injurious. The same cause produces damping or fogging-off with small or tender plants. If the temperature rises rapidly while the soil is comparatively cold condensation takes place on the surface and speedily affects the stem where it touches. A low temperature, even when approaching a frosty one, is not injurious of itself to ripe Grapes; but when the natural temperature rises suddenly while the Grapes are still cold and condensation takes place on them, as was so well explained by "A NORTHERN GARDENER" recently, injury very soon follows. The only safe plan is to just keep the pipes from becoming entirely cold and to run as if for your life to open the ventilators when the sun is likely to show itself.

Keeping a regular temperature of 40°, 50°, or any other fancied height is all nonsense. You cannot do it. If the outside air is 55°, your vinery with ripe Grapes must be 60°, or the fruit will soon rot from damp. Heating and ventilation attended to, the amount of moisture in the house is of little consequence. We are still (February 5) using Hanburgh Grapes which have been kept in a house with thousands of bedding plants which received an abundance of water two or three times a-week all through the worst winter months perhaps ever experienced. I must not, however, take too much credit upon myself for this, for a great deal belongs to the country,—Wm. TAYLOR.

THE WHITE LILAC,

AS PREPARED AND FORCED IN FRANCE.

The white Lilac, which is extensively used in the formation of bouquets in Paris from the month of October, has been an object of much interest. The cultivation of this shrub, the colour of which is lilac when grown naturally in the open air, appears a mystery to many who are not initiated into the secrets of horticulture. It is, however, quite simple and practicable even for modest amateurs.

The Lilac Charles X. is preferable to all others for this mode of culture; it alone is employed for this special culture. Take up in autumn a clump, or only a part,

according to the quantity required; pot all the shoots which in dividing the clump have good fibrous roots, and which especially shall have a head, or branches likely to make one. Place these to a foot long, or as much as is enough for the shrub to be sufficiently strong, and not too large, when in the following year it is to be placed in the forcing house. The subsequent pruning is to be regulated so as to form a handsome head to the plant. The plants are to be placed in a cold house or pit during the winter; afterwards they are to be plunged in the open ground, and attended to by shading and watering them, in order to secure good heads. At the end of August when they shall have finished growing select all those that are well set with blossom buds, and which it is intended to force; put them in a shaded place and suspend watering them so as to ripen the wood, and when the soil in the pot is quite dry and the wood has begun to shrivel, then is the time to begin forcing.

Place the pots on the floor in a corner of a stove or under the stages where they will be completely shaded, water them abundantly, and be careful to keep up the heat at not less than 70° to 80° to insure success. Those who specially cultivate this plant do so by thousands. Many nurserymen grow them to supply amateurs, and we think that those who wish to have those magnificent shrubs in flower a year earlier would do well to purchase them; they will then see in what state they are, and that will be a guide if they wish to experiment for themselves in the following years.

As to the shoots which are not sufficiently rooted to fit them for potting, they should be planted out and grown-on for use the next year.—(*Le Moniteur d'Horticulteur*.)

ROYAL HORTICULTURAL SOCIETY.

FEbruary 13TH.

THE Annual General Meeting of this Society was held last Tuesday in the Council-room, South Kensington, Lord Aberdeen, the President, in the chair. The members of Council present were Lord Alfred S. Churchill, Dr. Denny, Mr. Henry Webb (Treasurer), Dr. Hogg (Secretary), Mr. Haughton, Mr. Kellock, Major Mason, and Mr. Campion. Amongst the general body of Fellows were Mr. Edgar Bowring, C.B., Mr. Guedalla, Mr. G. F. Wilson, Mr. G. T. Saul, Mr. Shirley Hibberd, Mr. Godson, sen., Mr. De Castro, Mr. David Wooster, Mr. John Fraser, Mr. P. Liggins, Mr. H. Veitch, Mr. Maurice Young, Dr. Masters, Mr. H. J. Elwes, Mr. B. S. Williams, Mr. Arthur Grote, Mr. John Lee, Mr. Tweedy, Mr. Bateman, &c.

Mr. DICK (Assistant Secretary) read the minutes of former meetings, which were approved, and signed by the President.

Messrs. H. VERRON and J. LEE were appointed scrutineers for the ballot of members of Council and officers of the Society. The Report of the Council having been taken and read.

THE PRESIDENT said: Ladies and Gentlemen—Those who remember their Horace will recollect how a thousand lines were spoken by a poet standing upon one foot, and as the President of this Society I ought not to shrink from making to you a few observations in the same unfortunate position [alluding to the effects of his late accident]. You will all have read with satisfaction a statement in the Report of the actual work done towards the advancement of the science of horticulture. I draw special notice to that because the Council, like the rest of the Fellows, have read the disparaging remarks which have appeared from time to time as to the proceedings of this Society. Undoubtedly the unfortunate circumstances which have been the subject of so much conversation in this room have had to some extent a prejudicial effect upon the position of the Society. It is undoubtedly true a large portion of the funds, which might have been devoted to the advancement of horticultural science, have necessarily been applied to the maintenance of these gardens at South Kensington. It is true that the Journal of the proceedings of the Society, which all who are fond of horticulture have read with the greatest possible interest, has been discontinued; and there is no question that the connection of the Society with the South Kensington Gardens under the modern phase which it has unfortunately taken during the last two or three years has been prejudicial to the interests of the Society. This subject has been made one of unjust comment on the consequences of that union. It is not for me to defend it. It was proposed many years ago and advised by the late Prince Consort on the one hand, and by Dr. Lindley and other most earnest supporters of the Society on the other. There was a hope that the effect of this union would be to popularise science to a very great extent, and I cannot say that in my opinion those anticipations have been realised [hear, hear]. I doubt whether they were realised at the time when the Society was most prosperous, because I think what prosperity meant was a large number of subscriptions from South Kensington and the enjoyment of the pleasures and advantages of these gardens [hear, hear]. But

when you bear in mind the fact that you obtain 47,000 plants a-year from Chiswick for these gardens, you must not conclude that the reputation of the Society must be gone in a scientific point of view; but we must all feel that, having entered into this union, it was impossible lightly or easily to withdraw from it. In the first place it was absolutely necessary for us, as men of honour and principle, to do our utmost to give effect to the intentions of those who brought about this union. Even supposing there had been a failure of the object in view, there was still a sense of honour to be felt towards those who had advanced large sums of money in the hope of the concern or the union being a prosperous one [applause]. There were some persons who advanced nearly the sum of £50,000 on debentures, and there were also life-ticket-holders who paid down their money and whose claims could not be repudiated. It was thus the duty of those who had in their hands the management of the Society to do, while there was a vestige of hope left, their best for the general welfare of the Society, and to secure the interest coming due to the debenture-holders and to the life-ticket-holders. Well, you are all aware of the result of all this. We are now under a special lease for three years, during which time we cannot be extinguished. At the end of these three years, in the event of the annual sum of £10,000 not being raised, Her Majesty's Commissioners will be in a position to extinguish the Society.

Mr. W. HAUGHTON.—If the amount of one only be not £10,000.

THE PRESIDENT.—Well, we must show we have obtained subscriptions to the amount of £10,000. All we received from all sources last year was £5800, and you can judge for yourselves the amount of effort that must be made to secure the sum which is now required. It may be thought that the attempted absorption of the gardens by Her Majesty's Commissioners may lead to increased efforts so as to enable the Council to carry out their desire to promote the real objects of the Society both at Chiswick and South Kensington. If not, you will see that it is utterly impossible for the Society to continue in its present position. How can we remain as tenants bound to pay £2500 a-year which we cannot pay? When we have a burden of £2000 a-year, which ought to be paid to the debenture-holders, what use is it for us to remain here, when during the last year we were unable to keep up the gardens in a proper condition, when we had to cut down all our expenses and close all the entrances to the gardens but one? I think you will feel with me and the Council, that is not a befitting position for this Society to be placed in [hear, hear]. It is not right or proper that this Society should be constantly exposed to the charge that it is endeavouring to maintain a position it cannot maintain. If a man finds himself over-spending himself, it is his duty to make his income and his expenditure balance, and to give up every source of unnecessary expenditure. It is equally the duty of this Society to endeavour to square its expenditure and receipts by abstaining from trying to support and keep up gardens like these for which an adequate income is not provided [hear, hear]. I have stated here on former occasions, and I am glad to state it again, that having, by the assistance of the Commissioners, taken the Society from a state of debt and bankruptcy, I think it my duty to endeavour to keep the Society from incurring further debt. During the next two years we shall not, I am sorry to say, be able to keep the present gardens up to their former condition. We shall, I am sorry to say, be obliged to refrain from many things we would like to do for the extension of horticulture, but I think our great object during the next two years should be that the Society should not suffer in credit by entering into pecuniary liabilities it cannot discharge [hear, hear]. I wish you to understand that only for Her Majesty's Commissioners were should be involved in very heavy debt. The sum of £5000 advanced by Mr. Frake has been spent in discharging our debts, and you will agree with me that it is our duty to prevent the Society from again running into liabilities they have not the prospect of discharging or of getting any assistance towards discharging from the Commissioners. My view of the question is this, that unless the public generally, and especially in this neighbourhood, exert themselves to put us in a position to raise the annual sum of £10,000, it is impossible for us to meet our ordinary obligations; and I then think that the union between South Kensington and Chiswick ought to be discontinued at the end of three years. That is a fair notice, which ought to be clearly understood. I am glad to find the Report of the Council in its concluding sentence puts their position in clear language. With these observations I beg to move the adoption of the Report [cheers].

Mr. SHIRLEY HIBBERD wished to call attention to the balance-sheet. They should have had in their hands that day a full statement of accounts than that they had been furnished with. The balance-sheet did not include the £5000 received as a loan from Mr. Frake, and they had no account with respect to a sum of £1800. He should like to ask the Treasurer how it was that he had put in the hands of the Fellows such a statement of accounts as rendered it almost impossible for them to proceed with the business? Some years ago it was determined to

hold exhibitions in the provinces, but a Finance Committee, representing Her Majesty's Commissioners and the Council of the Society, determined that the Society's funds could not be applied to exhibitions in the provinces. Finding themselves in a difficulty the Society provided a fund of their own which came out of certain private pockets, sometimes in the shape of guarantees and also in the shape of earnings from distant places. The last exhibition at Bath left them in possession of £2000 altogether solely to be devoted to the promotion of exhibitions in the provinces. It was stated in the circular issued by the Council that these provincial exhibitions would be resumed; but now they had no money to carry them on. In 1873, Viscount Bury being then Chairman of Council, a sum of £1800 was borrowed from the provinces and transferred to the general funds of the Society, and in that very same year £1900 was paid in interest on debentures; so that the separate horticultural funds were turned to account to pay off interest on the debentures. But that should have been paid out of the surplus profits of the Society. The Society had no business to touch that money. He should like the Treasurer to tell them something of this missing £1800, because it should really be paid back to the horticultural funds by this time, so as to enable the Society to look forward to provincial shows with some prospect of success.

Mr. HENRY WEBB (Treasurer), said he thought Mr. Hibberd had answered the question about the £1900, for he told them it had been spent [a laugh]. He deemed it an improper thing to have taken the money from that fund, but it was done before he was Treasurer. There was a large sum of life-composition money taken, and he regretted very much it had been done, because, if it had not, they would have been able to go on without borrowing this money from Mr. Freate. Ever since, as by the Charter they were obliged to make the money appear from year to year in the balance-sheet, it rendered the balance-sheet to that extent inaccurate and misleading. There was no such fund, and in the accounts it appeared that they had a larger sum in revenue than they actually had. He regretted the balance-sheet had not been made out until the present moment.

Mr. HIBBERD asked the Secretary if he could furnish the meeting with a copy of the minute under which the money in question was improperly transferred.

The PRESIDENT.—All these proceedings took place before the existence of the present Council. They appeared in the accounts. It may be a subject for animadversion, but I cannot conceive what advantage can arise from discussing statements of accounts which have already appeared [hear, hear]. I think Mr. Hibberd has received a very clear and full answer as to this unfortunate sum, and no advantage can arise from reopening a question so long in abeyance.

Mr. GUEBALLA thought with Mr. Hibberd that a better statement of accounts ought to have been submitted to the Fellows.

The PRESIDENT.—I quite agree that fuller accounts ought to have been furnished.

Mr. GUEBALLA.—We should have received a printed statement of accounts. He should like to ask the Chairman how subscriptions were coming in, so they had heard so many reports on the subject. It would be well if the Fellows had some statement on the subject, as it might induce people to make an effort to increase the income of the Society.

The PRESIDENT.—I am happy to announce that we shall, in the course of this day's proceedings, proceed to the election of thirty-nine new Fellows [hear, hear].

Mr. H. WEBB.—And a great many of those who have withdrawn from the Society are coming back to it again [hear].

Mr. GUEBALLA said the noble Chairman had so clearly laid down their position, that he thought it best to go on and await the chapter of accidents. He should with pleasure second the motion for the adoption of the Report.

Mr. GODSON, sen., asked what would be the result if the £10,000 was paid in? In that case, what arrangement was there with the Commissioners?

The PRESIDENT.—I am glad you asked that question, because it is a very important question, and a full answer ought to be given to it and clearly apprehended by all persons present. Supposing the conditions of the lease are fulfilled by our raising the revenue to £10,000 a year and paying an annual rent, it will be impossible for the Commissioners to put an end to the lease, and it will be our duty to continue the connection; and, for one reason among others, that that is the only chance that the debenture-holders have of receiving interest on their £50,000. So long as the Society receives a sum over and above the cost of maintaining the gardens, that sum should be paid to the debenture-holders; that is their sole right. The only legal right to the payment of the capital arises from two sources. One is—if at the expiration of the lease in 1891 the Society fulfils all the conditions of the lease, and the Commissioners then choose to extinguish the debt, the Commissioners will be bound to pay one half the debentures. That is one half. The other half is by putting aside excessive receipts over the payment of the interest due to the debenture-holders during the continuance of the

lease and over the annual interest. A part of that excess is put aside to redeem the capital of the debenture-holders. I do not say that the second part of that will carry very much comfort to the minds of the debenture-holders; but there is this much in it, that it shows us it will be our duty to carry on the gardens as honest men, so that we might prevent a substantial security to the debenture-holders [hear, hear].

Mr. GODSON.—Are we safe at the present moment in the continuance of our occupation of the gardens? Supposing that £10,000 a year is not raised until the term expired, what then?

The PRESIDENT.—It would be two years until the termination of the three years.

Mr. HAUGHTON.—From Christmas next until the Christmas following. Now if the income of that period comes up to the indicated figure the gardens will be continued.

Mr. GODSON observed that there was one thing still regarding their position which it was well to have determined. Supposing that £10,000 annually was not received, what would be the result as to all their property? Would their possession last for three years or for two years?

The PRESIDENT.—That will depend upon the action of Her Majesty's Commissioners.

Mr. GODSON.—That is exactly what I want to know about.

The PRESIDENT.—If at the end of that time we are not in a position to pay our rent Her Majesty's Commissioners will be exactly in the position of other landlords, and can, as a matter of course, terminate the lease.

Mr. GODSON.—Then we are at their free will?

The PRESIDENT.—Yes, we are.

Mr. GODSON then remarked that the Report of the Council was the most extraordinary one he had ever seen presented to a meeting. The Council started their Report by saying they borrowed £5000.

The PRESIDENT.—But that is a liability of the Commissioners—it is not a liability of the Society.

Mr. GODSON.—I am very glad to hear your explanation.

Mr. TWEEDY wished to have some explanation about £2300 expenditure on the Chiswick Gardens, which was at one time a most fashionable resort. It seemed to him that the Chiswick Gardens had ceased to be of any use to the Society [no, no]. What he would suggest was that they should sell the Chiswick Gardens [cries of "no," and laughter]. Well, he should much rather that these gardens were sold and some of the money appropriated to the payment of the debts of the Society than that their existence should be continued. He did not see the means of keeping up the cost of the establishment.

The PRESIDENT.—My old friend proposes we should give up these gardens. I have mentioned the 47,000 plants have been brought from them to these gardens. He has referred to the past times of the Chiswick Gardens when during some few years it was a fashionable resort, but now the gardens are turned to use for scientific experiments and for horticultural purposes. As to selling the Chiswick Gardens, I entirely disagree with my friend [cries of "hear"]. I cannot see any good effect such a proceeding would have [hear, hear]. I do not know whether my friend saw the undignified entry of the President into this room, because it really looked like the present position of the Society. One of his legs was firm and stout, and that I conceive to represent the Chiswick Gardens [laughter and cheers].

The other leg was weak, tottering, and useless, which bears a remarkable resemblance to the South Kensington Gardens [more laughter]. The crutches I take to represent the Commissioners, who alone interfered between us and bankruptcy [hear, hear]. Now if the crutches gave way the sound leg would be reduced to the condition of the other one, and I do not know what the unfortunate man—or, carrying out the simile, the Society—could do without the crutches, which represented the Commissioners who alone interfered between us and bankruptcy as I stated before [hear, and cheers].

Mr. LINGGIE said they appeared to forget that in the old times they were not able to meet their expenses, and that in order to put themselves in proper funds it was necessary to do something more than maintain Chiswick Gardens. If in consequence of the failure of the Royal Horticultural Society they were to go back to Chiswick Gardens, it would be more detrimental to them than anything they could do. He had been always one of those who thought they should cultivate the connection with South Kensington, not with respect to horticultural gardens so much as with respect to affording them a large income [hear, hear]. The South Kensington Gardens were in the midst of London, and of those who cared for little but for London and its pleasures. The money of these people was just as desirable as the money of horticulturists, but it was only by a union of the two that the Society can be made a paying concern [hear, hear]. He hoped some measures might be taken to raise the income, so as to enable the Society to continue its connection with the Commissioners.

Mr. WOOSTER observed that the Society was losing in reputation by the impression which was abroad, that there existed no security for either capital or interest due to the debenture-holders.

THE PRESIDENT.—Would you suggest what possible property this Society could offer as security for the £50,000 debenture debt?

MR. WOOSTER said there was in the agreement with the Commissioners a clause touching the life Fellows which was for the purpose of forming a sinking fund for the ultimate extinction of the debenture debt. He only wished to remind his lordship and the other Fellows of this stipulation, and that the impression to which he had alluded did very serious injury to the future prospects of the Society. The original interest of the debenture-holders was 5 per cent., but after the expiration of a year that was thought too much, and then in July, 1861, there was a letter sent to the debenture-holders proposing a reduction of 1 per cent. The debenture-holders consented to that proposition, and he thought this was really a legal debt due by the Society to those who had taken the debentures, and that they ought to be secured.

THE PRESIDENT.—What property have we available for paying off the debt?

MR. WOOSTER.—I am merely suggesting that the impression which is abroad might probably prevent the public from joining the Society.

THE PRESIDENT.—But the practical result is this, that if the Fellows subscribe they will pay the debenture debt. That is the practical solution of the question. What other solution can there be?

MR. WOOSTER further observed that it was a remarkable circumstance that in the Report there was no mention as to the non-fulfilment of the conditions of the circular issued the 17th of March, 1873, touching a certain series of lectures which was to be given by the Society.

THE PRESIDENT.—My answer to that last remark is that the circular was sent to all the various Fellows, and we only got one answer [laughter]. We naturally did not think it right to establish lectures for one auditor [laughter].

MR. GEBDALLA thought the Council ought to disown the action taken by Mr. Wilson. Some notice ought to be taken of this by gentlemen on the other side of the table.

MR. WILSON rose to say he thought they were considering the subject that day almost exclusively from a South Kensington point of view, as they were told the hope of the Society depended upon collecting funds from the neighbourhood amounting in one year to £10,000.

THE PRESIDENT.—I said the hopes of the Society if it were to continue.

MR. WILSON said the letter in the *Times* of the 19th January was perfectly conclusive. They kept on trusting to the neighbourhood of South Kensington instead of going at once to the great body of horticulturists throughout the country. He wanted to see a large number of horticulturists—say five thousand country horticulturists, or horticulturists from town and country, come forward and give their names as supporters of the Society [hear, hear].

A LIFE FELLOW said he had been told the Society had always been in difficulties. Now, supposing such a state of things as that the Chairman had sketched out—that Her Majesty's Commissioners detrained upon the gardens and turned the Society out of them—in what position were they likely to be in then? because, from all he had ascertained, if they went back to Chiswick they would go back to the old condition of debt and difficulty.

THE PRESIDENT.—I may say I think that if the Society were simply a scientific society and unconnected with South Kensington it would get a good deal of independent support on that ground [hear, hear]. I have heard frequently one reason why people do not join these gardens, and that is that they will be bound hand and foot to South Kensington, and that the whole object here is to keep up the gardens in a magnificent state. That impression I am told is very strong, and that it cannot be removed without disuniting the two establishments. But I would do nothing to disunite the two, but endeavour to preserve the union [hear, hear]. But I will say certainly that if that did take place a large number of horticulturists would be induced to come forward and join the Society [cries of "hear, hear."]

Then we must recollect in the case of Chiswick that it had a large debt in spite of many sacrifices. A large scheme was set on foot in 1860, and a great deal of money was spent in scientific proceedings, whilst our debt at South Kensington has not arisen from the prosecution of scientific research. I am told that for several consecutive years they had at Chiswick beautiful weather, fine summers, and hence large gatherings at the Chiswick Gardens, and of course the receipts were very large. Then came three or four successive years of bad weather with very large expenditure and next to no receipts, during which a large portion of the debts were incurred. Since these days horticulture has spread enormously. I should not be surprised that there should be five thousand men ready and willing to give £5000 for the purpose of real scientific horticulture, but I think it much more likely to be got from members of the Society where there is a scientific society united for social purposes with South Kensington [hear, hear].

LORD ALFRED S. CHURCHILL.—In proposing his scheme, Mr. Wilson will recollect we are tied hand and leg to these gardens until two years expire, or until we raise our subscriptions to a certain amount. I can hardly agree that, if we were once freed of these gardens, we would get a large amount of horticultural support from the country. I have recently returned from Dublin, and there they maintain a horticultural society, and one that is in a most flourishing condition. They have their scientific meetings, they give away prizes, and do all the scientific work which a horticultural society ought to do. I said to a friend of mine the other day in Dublin, "I should like to see your gardens." "Oh," said he, "we have got no gardens" [laughter]. The fact is, they work on without gardens, and subscribe together for a common purpose. Therefore, if that answers in Dublin it ought to answer here; but, in addition, we have got Chiswick Gardens, which were considerably reduced in size when we spent our money so prodigally, so that we can maintain our gardens at a reduced cost. If we once got rid of these gardens at South Kensington our expenses would be reduced considerably, and we could keep the other gardens for scientific purposes [hear, hear]. If we could get rid of the incubus of these gardens Mr. Wilson's scheme must work. At any rate, under the circumstances we must do the best we can, and in view of that we have proposed various modifications in your subscriptions.

MR. H. VEITCH said his name unfortunately appeared as one of those who gave their sanction to Mr. Wilson's scheme; but he was not prepared to go the length to which Mr. Wilson had gone. He regretted that Mr. Wilson appeared in the press in the way he had, because it seemed to him (Mr. Veitch) that Mr. Wilson was trying to coerce the Society into adopting a policy which would be very dangerous to the Society [hear, hear]. He wished so far to disavow his intention to adopt Mr. Wilson's plan. Mr. Wilson told them that a great body of people would come from the country to subscribe to the Society, but in the list which Mr. Wilson had recently circulated—that of the 5th of January last—he found that the whole number of people amounted to only 373—not a very large number, considering the circulation the scheme had got, and out of these 373 he should think about one-third of them were already members or Fellows of the Society. Now, that would reduce Mr. Wilson's list very considerably [hear, hear]. With regard to the Society itself, it seemed to him that neither the horticulturists pure and simple, nor the horticulturists of South Kensington, can by themselves keep the Society going. It could only be kept up by all working together [cheers]. They wanted along with horticulture the extras, so as to make the building at South Kensington as attractive as they possibly could. They must bring their fruits and flowers there to be exhibited, for it was their interest to do so [hear, hear]. As regarded the gardens themselves, they did not actually want them. They wanted a place for their meetings and for the Council, to which they all could come. On the other hand, if the South Kensingtonians would come forward to liberally support the institution, he thought it would be the best thing for the Horticultural Society to keep up the gardens, so that they could be enjoyed. If the people would only come to-morrow (Wednesday) afternoon from the country, he could promise them a very beautiful show, and that they would find not only a horticultural treat but a band of music playing for their pleasure and enjoyment. That was what he called a very proper amalgamation [hear, hear]. There was one point on which he should like to ask a question. On page 3 of the Report, in the last paragraph, it is stated—"The provincial shows stand on a more favourable footing, and the Council have now under consideration when and where the next shall be held." He should be sorry to hear that nothing was to be done as to provincial shows. It did seem hard that, when the money had been fairly earned, the firstfruits of the provincial shows should have been forcibly taken away for other purposes [hear, hear]. If they had the money in hand the provincial shows would be held, and judging by the results of former shows, they would bring in a very fair income to help the Society. He should like to know what steps have been or are being taken towards holding provincial shows this year; on what footing were they to be, and what amount of consideration the Council had given to the subject?

THE PRESIDENT.—I am hardly in a position to give a distinct answer to that question. All I can say is we are in communication with one of the principal cities of England, and have a very strong hope that we shall be able to do something successfully [hear, hear], and lay perhaps the foundation of a new future for the Society. I have no doubt if we are successful we might have a guarantee fund which would put us out of all difficulties of a financial character. If some surplus remained we would have the nucleus of a capital sum which would enable the Society to have a show—a provincial show—annually [hear, hear]. Warned by the past it is the intention of the Council to invest in trustees any surplus they receive, and to have due application for the same [hear, hear]. Let me correct a mistake I involuntarily fell into. I said that at the time the Society

joined South Kensington they had a debt of £10,000. Dr. Hogg, who knows much more about the matter than I do, tells me that though the original debt was £10,000, it had been reduced by the sale of houses in Regent Street, and the actual amount of debt remaining was £5000. But whether it was £5000 or £10,000, it shows that the method of carrying on the Society was not successful. Good finance, which is everything in the management of a kingdom, is as necessary to a society [hear, hear]. I am of opinion that all this indirect and unnecessary expenditure ought to be abolished. It is through the assistance we have received from Mr. Veitch and others that we have been enabled to have our exhibitions, and I am sure the Society cannot be too thankful for the assistance received from Mr. Veitch and other gentlemen [applause].

Mr. ELWES said he thought there was no reason whatever why there should not be a perfectly fair union between the South Kensington and the Horticultural Fellows; and the South Kensington Fellows should remember that after all, the Society being a horticultural one, horticultural objects would be the first objects of the Society. By the action of the Zoological Society it was evident such a union was perfectly possible. No Society was more popular, and, although some of the members worked in a purely scientific groove, matters were so arranged that the Society has attracted three-fourths of their members who did not care a straw about zoology, but who joined the Society for the purpose of attending the gardens on Sunday [laughter]. They also opened the gardens at a low figure on Whit-Monday and other days, and so attracted a large number of the people of London to them. Although it was impossible for the Horticultural Gardens to have so much general attraction as the Zoological Gardens, if the South Kensingtonians wished them to be kept up they could do it by contributing their fair share, which would enable the Fellows of the Society not only to carry on the gardens as they ought to be carried on, but to do good horticultural work besides.

The PRESIDENT then put the question, "That the Report be adopted," and it was carried with one dissentient (Mr. Godson, sen.) Thirty-nine new Fellows were then elected.

The result of ballot was announced by the President. Those recommended by the Council were declared elected as follows:—President, Lord Aberdare; Treasurer, Mr. H. Webb; Secretary, Dr. Robert Hogg; Expenses Committeemen, Mr. F. Campion, Mr. H. Webb, and Mr. W. Haughton; Auditors, Mr. J. Lee, Mr. H. Little, and Mr. James F. West.

The PRESIDENT, referring to the proposed alterations of the bye-laws, said the Council had, as a last effort, to conciliate the inhabitants of that neighbourhood, and so far as they could ascertain by the expression of feeling, the proposed alteration of the bye-laws would have a good result. They had just elected the good number of thirty-nine Fellows, and in addition to that fact they had a great many of those who had left the Society returning to it, so in that respect the affairs of the Society looked more promising [hear, hear.] He thought they should unanimously adopt the new bye-laws.

Dr. HOGG (Secretary), said it was proposed to alter the 14th and 15th bye-laws, first by suspending the payment of the entrance fee, which was provided for by the 14th bye-law. The 15th bye-law provided that no Fellow whose entrance fee was not paid should be entitled to vote at meetings of the Society. It was now proposed to strike out the words "when the entrance fee has not been paid."

The PRESIDENT in reply to Mr. Veitch, who put a question respecting one-guinea membership, said he had not been able to attend the Council meeting lately, and was therefore unable to say what attention had been given to that subject. He took the view of Lord Alfred Churchill on the matter—that it would be an excellent plan, if this were simply a horticultural society, to have a guinea membership [hear, hear].

Lord ALFRED S. CHURCHILL said the guinea members should have all the privileges of Fellows except that of voting at the meetings of the Society. It had been felt that it would be open to any person, who, say, had strong objections to the Council or policy of the Society, to induce people to become guinea members, in order to control the action of the other Fellows. The Council thought they should give to guinea members all the privileges of personal admission to the gardens and to shows, exhibitions, &c.; in fact, all existing privileges except that of voting at the general meeting. He was glad to say two members had been elected according to this plan.

Mr. GONSON asked if the guinea subscription ticket was transferable.

Lord A. S. CHURCHILL said it was not. Any guinea Fellow who desired to exercise his voice in the management of the Society could do so by paying an additional guinea.

The alterations in bye-laws 14 and 15 were then agreed to.

The PRESIDENT observed that he thought in the present position of the Society the entrance fee would operate in preventing people from joining the Society, and that it was wise therefore to exercise the power of doing away with an entrance fee [hear.]

Lord ALFRED S. CHURCHILL wished to mention an additional

source of income to which they looked forward with hopeful anticipations. Throughout the whole country there was a large number of local horticultural societies, and the Council were desirous of affiliating them with the Royal Horticultural Society. Indeed many of them had been affiliated to the Society for years, and were put in the position of individual subscribers. The Council proposed to give gold or silver medals for distribution in the local shows [hear, hear]. That would enable the local societies to distribute as rewards for merit at their shows medals of the Royal Horticultural Society. He hoped that the result of the proposition would be, as he did not doubt it would, to bring to them a large number of local horticultural societies scattered all over the country [hear, hear].

Dr. DENNY said he wished to explain with reference to refunding the money which was taken, that the Council could not refund it out of the money which was lent.

Mr. GONSON.—Did you not apply that money to pay your rent?

The PRESIDENT.—No.

Dr. DENNY further explained that the Finance Committee, consisting of three of Her Majesty's Commissioners, objected to any money being spent on provincial shows. He could not believe but that if the matter had been properly put before the Finance Committee the money might have been raised by guarantee; but he did not believe the Commissioners would allow them to refund the money.

Mr. H. WARR (Treasurer).—If I ever get any provincial show money again it shall be properly invested [laughter], and not at the dictation of President, Vice-president, or anybody else [renewed laughter].

Mr. H. VEITCH.—I promise you that if you get up good provincial shows we will have the money to invest [hear, hear.]

A cordial vote of thanks was then given to the noble President, and the proceedings terminated.

REPORT OF THE COUNCIL.—Notwithstanding the many disadvantages with which the Council have had to contend, they have the satisfaction of congratulating the Society on the progress that has been made during the past year in the advancement of scientific and practical horticulture.

At no time in the history of the Society has greater interest been manifested in this important pursuit, both commercially and as an intellectual recreation; and the operations of the Society have been directed not only to promote and encourage, but to anticipate the growing taste for horticulture by all the appliances it has at command.

The Scientific, the Fruit, and the Floral Committees have met during the year without intermission and worked assiduously at their respective branches; and under their superintendence and direction much valuable work has been done in the garden at Chiswick as well as at the meetings at South Kensington.

The meetings of the Scientific Committee have been well attended. Many most interesting facts in the morphology and physiology of plants, as well as the branches of teratology and pathology, have from time to time been brought before the meetings, and the investigations of the Entomological Department, with reference to the injuries produced by insects on plants, have been of the greatest importance. Mr. Smith's observations on the resting spores of the *Peronospora*, referred to in last year's report, were on several occasions fully confirmed, while the facts afforded by the late lamented Mr. Snee's very numerous microscopical preparations of the aphides which attack Potatoes, and which were found to be infested by the *Peronospora* actually producing oospores *in situ*, tended greatly to confirm the accuracy of Mr. Smith's researches, while his discovery of resting spores in the *Fusicarpium Solani*, a fungus which is sometimes almost as destructive as the *Peronospora*, demands especial attention. Amongst other matters the grafting of a dwarf Sunflower on the Jerusalem Artichoke, and that of different species of Solanum on one another, as effected by Mr. Maule of Bristol, though requiring confirmation, were of high interest; while Dr. Hogg's attempt of a classification of Apples was brought before the Committee and thoroughly discussed, its Secretary bearing ample testimony to its usefulness and to the credit which its operations ought to confer on the Horticultural Society.

The Fruit Committee has also been engaged in doing good work in its department, and the reports of the experiments that were conducted at Chiswick under its superintendence will be found in the part of the Society's *Journal* which has recently been issued. These consist of elaborate trials of 214 varieties of vegetables. Besides the reports that are already published there are others in preparation which will treat on 150 varieties of Strawberries.

The large collection of cordon-trained Fruit trees, covering the west wall of the garden at Chiswick, fruited last season for the first time, and of these many notes were taken which will furnish matter for a special report. This is the most complete collection of Cherries that can be obtained, and consists of some

hundreds of varieties, all of which will be proved as to their adaptability to the climate and their uses in this country. The cordon-trained Peaches on the south wall show a great promise of fruit for the present year, which will enable the Fruit Committee to compare them with one another, to ascertain their merits and to settle their synonyms. The crop of Peaches in the large orchard house was most satisfactory, as well as that of the Vines in the large conservatory.

The distribution among the Fellows in this department were 3851 packets of cuttings of fruit trees.

The work of the Floral Department has been by no means unimportant from a practical point of view. The most useful of the observations made during the past year have been those relating to the double-flowered Zonal Pelargoniums, a class which has rapidly increased in numbers, and of which it was highly desirable that a knowledge of the best sorts should be obtained. This has now in great measure been secured, as will be seen by a reference to the report in the recently-issued number of the *Journal* of the Society.

Some modification has also been made in the mode of testing the merits of the new varieties of Zonal Pelargoniums, of which an extensive series has, thanks to the raisers and growers of these plants, been annually brought together at Chiswick for some considerable period. Instead of bedding-out all the novelties the first year, as has hitherto been done, the Floral Committee thought it would be more desirable to grow the new sorts for the first year under glass, in order to test their suitability for pot culture; and the second year, when better established plants would as a rule be attainable, in the open air, in order to ascertain their adaptability for bedding purposes. This has accordingly been done, and it is proposed to follow the same plan in future.

The actual trial collections consisted of 165 varieties of Double Pelargoniums, 39 sorts of Ivy-leaved Pelargoniums, and 182 sorts of new Zonal Pelargoniums. For the opportunity of procuring these very complete collections of Pelargoniums the Council were indebted to the Pelargonium Society.

The distributions in this department to Fellows have been 2900 packets of various kinds, 1600 packets of cuttings, and 20,000 packets of seeds. It has been found that the distribution of plants gives much greater satisfaction to Fellows than the former mode of balloting for them.

A valuable collection of ornamental hardy herbaceous plants has been formed, and arrangements have been made for making beds of the popular old florists' flowers, such as Ranunculuses, Anemones, Carnations, Picotees, Auriculas, &c.

The number of plants that was supplied from Chiswick for the decoration of the conservatory and gardens at South Kensington was 47,872 up to July 18th, when the supply was discontinued, and the estimated value of these is £901 7s.

The state of the subscription list has not as yet been such as to justify the Council in issuing the usual schedules of flower shows, but they hope that it will ere long enable them to do so on a scale creditable to the Society. Although the great shows are, except under unusually favourable circumstances, attended with considerable loss, the Council, having regard to the general feeling of the Fellows in favour of these shows and their practical use in popularising horticulture, have decided to continue them in as efficient a manner as the funds at their command will permit. The provincial shows stand on a more favourable footing, and the Council have now under consideration where and when the next shall be held.

The Council will continue to encourage the fortnightly meetings, which form so great an attraction to all lovers of flowers, fruit, and horticulture generally. At these meetings may be seen all the novelties that have been collected by commercial or private enterprise from every part of the world, and also many of not less interest which art has produced in our gardens at home. The large attendances of Fellows and their friends that are usually seen at these meetings are an evidence of the interest that is taken in this part of the Society's work. To make these meetings even more attractive it is intended to try the experiment of holding them in the conservatory, and to have a military band in attendance.

Through the liberality of many of the exhibitors and some distinguished amateurs, Fellows of the Society, who have from a spirit of devotion to horticultural science supported it at great personal expense, the Council were enabled in July and November of last year to present two as grand exhibitions as have ever been seen in the gardens at South Kensington, and they have reason to believe that it is in contemplation to act in the same liberal manner some time during the present season.

The agreement entered into with Her Majesty's Commissioners in April last authorised the Royal Horticultural Society to borrow £7000 upon their guaranty of repayment in case they resumed possession of the gardens. The Council have borrowed upon this security £5000, which enabled them to pay outstanding liabilities, prizes, and medals; so that on 31st December last the Society had a balance in hand more than sufficient to

pay all their outstanding liabilities. The Society may be said to have commenced this year without debt or liability (except that attaching to surplus income in respect of debentures), which has not been the case for very many years past.

On the other hand, the Council have to regret that the receipts of the gardens have not proved sufficient to pay the interest on the debentures.

The strictest economy has been exercised—salaries and out-goings have been reduced by about £1000 a-year, and towards the close of last season it was thought advisable to reduce the expenditure still further by closing the entrance on the west side of the gardens. This has, however been re-opened, and will so continue as long as funds will admit.

The Council have, in their circular of the 21st December, 1876, so recently addressed the Fellows on their position with reference both to Her Majesty's Commissioners and the debenture holders, that they deem it to be unnecessary to return to the subject, more especially as that position remains unchanged. They content themselves with reminding the Fellows that, while their connection with South Kensington subsists, they are bound to do their utmost to obtain an income sufficient for the discharge of three distinct obligations—viz., the maintenance of the gardens, the payment of interest on debentures, and the payments of rents to the Royal Commissioners. In spite of all their efforts their receipts during last year have sufficed for none of these purposes. Not only did the debenture holders and the Commissioners remain altogether unpaid, but the Council were obliged, by a necessary regard for economy, to make an inadequate provision for the maintenance of the gardens and their enjoyment by the Fellows. It appears to the Council, and they trust that in this view they will be supported by the Society, that, unless sufficient funds are forthcoming for the fulfilment of their obligations, a proper regard for the dignity no less than for the scientific interests of the Society, dictates the earliest possible retreat from a connection which was entered into with so much hopefulness and with such fair prospects of enlarged utility.

A LARGE OAK.—One of the finest specimens of the English Oak in Herefordshire, if not in England, is, says the *Herefordshire Times*, about to fall under the auctioneer's hammer. This fine Oak, of which a photograph and interesting account appeared in the "Transactions of the Woolhope Club" some years since, is remarkable not only for the beautiful symmetry of its growth, but for the enormous quantity of timber it contains. Viewed at some distance, however, it fails to create much surprise, and it is only on walking round the trunk and looking up to the height at which it sends forth its huge branches that you begin to realise the enormous dimensions of the tree, which represent some 25 feet in circumference, and contains 1200 feet of timber. Until within the past eight years the tree was in such a healthy growing state that it could not be said to have arrived at the prime of life, when it was struck by lightning. A sight of this grand old tree and other magnificent trees on the estate will well repay a visit to Tyberton.

SEAKALE.

SEAKALE (*Crambe maritima*) is a native of the shores of Britain, and has been cultivated for more than a century, yet it is seldom found except in the gardens of the wealthy, and in those often planted in some corner or out-of-the-way place. Considerations, such as tidiness and the facility for applying the forcing or blanching material, have frequently caused it to be planted in the worst possible situations for its free growth.

Seakale requires an open situation and a generous soil. Stiff soils are unsuited to its cultivation, though by the addition of sand or ashes (charred refuse being excellent), the soil may be rendered sufficiently friable. The best soil, however, is a deep light loam or vegetable soil, especially a sandy one. My plan is to trench the soil to a depth of 2 feet, enriching with manure as the work proceeds, spreading sand on the surface, that material finding its way downward quite fast enough if mixed with the surface soil.

The seed is sown early in April in drills 15 inches apart, covering the seed about 1½ inch deep, placing three or four seeds at every 9 inches to make sure of plants appearing at those distances. Thin out the plants after they have formed rough leaves, leaving the strongest 9 inches apart, keeping clear of weeds during the summer, and watering with liquid manure during dry weather after May. Nothing invigorates Seakale so much as dressings of salt or nitrate of soda, applying broadcast half a peck of salt to 30 square yards, and 1 lb. of

nitrate of soda to the same quantity of ground. The dressings may be applied in March and at the end of June or early in July. Both are good against slugs. By the autumn many of the plants will have crowns large enough for forcing. When the leaves part from the crowns freely dig up the roots, placing them up to the crowns in pots or boxes. A 12-inch pot will accommodate half a dozen plants, keeping the crowns about an inch from the sides and the same distance below the rim of the pot. If the pots are to be placed in a dark place there is no need to cover them, but if to be placed in the light we must invert over each another pot, and tie round the crevice a strip of canvas so as to exclude light. Any house or place having a temperature of 50° to 55° is suitable. I find it necessary to apply tepid water about once a week when the crowns are placed in soil upon the floor of a Mushroom house. The soil should be moist when used, and be kept moist, or the produce will be hard and stringy. Though 55° is the most suitable temperature for producing fine Seakale in about three weeks, yet those having the accommodation of a greenhouse or any place with a temperature of 45° may grow produce of high excellence. A temperature of 45° to 50° will insure Seakale fit to cut in four to six weeks, the latter period in early winter, the former after January, 50° to 55° in three to four weeks, and 55° to 60° in a fortnight to three weeks, it being longer in growing in autumn or early winter than in the spring. I put in crowns every fortnight sufficient for producing "Kale" daily from November to April inclusive.

In respect of blanching in the open ground, there is no better plan than to hoop over two or three rows and cover with straw or long litter 6 inches thick. Covering the crowns with pots in the orthodox fashion answers well, the pots having movable lids. Old plants become weakened by a protracted season of forcing, and it is well to bear in mind that superiority marks the produce of roots which have not previously been forced. Yet those who can command leaves and stable litter in sufficient quantity may pursue a practice even if it is antiquated, troublesome, and uncertain.

When Seakale is intended to be forced upon the ground or blanching by pots the rows should be 2 feet apart and the patches 2 feet asunder. The plants may be placed three in a triangle at 6 inches apart, or a ring may be drawn 6 inches in diameter and 1½ inch deep, seed being placed therein, and the plants be thinned to three or four in each patch.

In case of a scarcity of covering material and the absence of pots, Seakale may be blanched quite well by covering the bed before growth takes place with sand, ashes, or cocoa-nut refuse—in fact, any light material—to a depth of 9 inches or a little more to allow for settling, and when the leaves show through the covering material the "Kale" may be cut, freeing it from dirt by washing at once; but a more cleanly method is to cover 6 inches deep with dry leaves, and a little litter to keep them from blowing about, and the shoots will raise the leaves, indicating which heads are first ready for cutting. Seakale thus produced is generally of superior quality. Blanching is resorted to, to make the head more delicate in appearance and flavour, yet the heads uncovered are equally good, having a full rich flavour as compared with the blanched produce. The heads or sprouts should be cut when 4 to 6 inches in length, the object being to have them short and crisp.

In taking up the plants for forcing, all having crowns less than an inch in diameter should be rejected for that purpose, and be laid in a thin heap covered with soil until a convenient time for planting, which may be done any time when the ground is in good working order until April. They should be planted in rows 15 inches apart and 1 foot apart in the rows, the crowns to be slightly covered with soil; but before planting cut off with a knife the crown bud, for unless this precaution be taken a majority of the plants will run to seed, and good crowns cannot be expected from such, even though the flowering stem be removed. The cutting off the crown will cause other buds to start not having the flowering tendency. These plants will give fine crowns for the succeeding winter forcing. Any plants not taken up when a year old for forcing should have their crowns cut off in February or March as a precaution against running to seed.

Plants which have been forced should be withdrawn from the heat so soon as the heads are cut, or they will start into a second growth, which is not desirable if the plants are to be forced the following year; but it is undesirable to take the plants from a temperature of 55° and plant them in cold wet soil at once. It is not, of course, necessary to harden off plants in March or April before planting. I have plants which have

been forced seven years consecutively, and they are apparently good for many years to come; but they become so large in the rootstock as to be less handy than younger plants.

Plants may also be increased by planting portions of the roots. The younger the plants which the roots are taken from, the healthier and better plants they are likely to give. Small roots may be cut into lengths of 4 to 6 inches, allowing the thickest end to be about an inch beneath the surface. They may be placed in a heap as detached in taking-up, and be covered with soil, planting in February or March—planting all together rather than in small quantities, as would be the case were the root-cuttings put in as the parent roots were taken up for forcing. Plants raised from cuttings will perfect some crowns fit to force by the following winter, and if cut over in spring and left another season they will afford very fine crowns. To secure plants for forcing without interruption some litter should be placed over the surface of the beds in December to prevent the ground being frozen, or a number of plants may be taken up and stored in moist sand in a cool shed until wanted, but it is preferable to lift the plants as required.

In taking cuttings of the roots, select only the small, clean, healthy parts. I find the best roots for this purpose are had in digging the ground for replanting, they being carefully picked out in the digging, and consequently are the extremities of the roots young and healthy.—G. ABBEY.

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

TELEBIA OCCIDENTALIS.—"T. occidentalis is the West African representative of the East African species, distinguished by the triplicately leaflets, short ovary, short calyx-lobe which are simply serrated, the smaller more open white corolla with smooth fringes and a red-purple eye, and by the few broad wings to the fruit; the fruit of T. pedata having no wings, but many very deep grooves. It is cultivated in West Africa for the sake of its seeds, which are boiled and eaten by the natives, and have been imported as oil-nuts into England. We have dried specimens from Sierra Leone, Abeokuta, Old Calabar, Fernando Po, and Angola, where it was found by Welwitsch, growing commonly over littoral hedges of Euphorbia aphylla. Our plant was raised from seed presented by Mr. Tserman, late of the Liverpool Botanic Gardens, in 1870; it flowered in the Kew Palm House in September, 1876."—(Dot. Mag., t. 627.)

MASSEVALLIA ATTENUATA.—"M. attenuata is one of Mr. Veitch's introductions, and flowered in the Royal Gardens in December, 1874, from specimens presented by Mr. William Saunders. Reichenbach remarks that the dried native specimens have the perianth glabrous within, whilst that of the fresh ones is finely velvety; the contrary of which is frequent in *Massevallias*."—(Ibid., t. 627.)

LIVISTONA AUSTRALIS.—"It is the most southern Palm of the Australian continent, reaching the snowy range in lat. 37° 30' S. when its trunk attains 80 feet in height, and extending thence along the west coast to the Illawarra River, in lat. 34° 45' S. It flowered annually at Kew, in the spring months, for many years. The fruits received from Mr. Hill, of the Brisbane Botanic Gardens; they resemble specimens brought by Brown, preserved in the British Museum, except in having a thicker and harder pericarp."—(Dot. Mag., t. 627.)

XANTHISMA TEXANUM.—"A very handsome Centaury-like hardy annual, with golden flowers, discovered in Texas some fifty years ago, and since found by many collectors, but never introduced into European gardens till within the last few years. It was published both in Europe and America, and as a new genus, first as *Xanthisma* by the elder De Candolle in the 'Prodromus' in 1836, and in about 1842 as *Centaureidium* by Torrey and Gray in the 'Flora of North America.' *Xanthisma* is closely allied to the great American genus *Helopappus*, which extends from California to Patagonia. The figure in 'Marcy's Expedition' is a very bad one, and represents the pappus as two distinctly double, the corolla of the ray as acute, which is owing to the margins being involute in a dry state; it omits the hairs on the achenes, and the minute serratures of the foliage. This plant flowered in Kew in November last."—(Ibid., t. 627.)

DRIMYDIUM KIRKII.—"In 1871 Dr. Kirk sent to Kew from Zanzibar bulbs of two species of this curious and little-known genus. One of them proved to be *D. botryoides*, described in the 'Linnæan Proceedings' from a couple of poor specimens, without any locality, in the collection of the late Judge Blackburn of Mauritius, and the other, the present plant. All the

known species of the genus resemble one another very closely in habit and flower; but there are two types of leaf, one with a distinct petiole and an oblong blade, after the fashion of a *Eucharis* or a *Griffinia*, a type of form very rare in Liliaceae, and the other with the blade narrowed gradually from the middle to both ends and not furnished with any distinct petiole. This is the first species of the latter group that has been brought into cultivation. It flowered at Kew first in July, 1873.—(*Ibid.*, t. 6276)

RHODODENDRON.—*Princess of Wales* "bred from *R. jasminiflorum* by the Messrs. Veitch & Sons of Chelsea. The original cross yielded the well-known useful decorative plants *Princess Royal*, *Princess Helena*, *Princess Alexandra*, &c.; and as the result of a subsequent cross, there has been obtained through these a race with larger flowers, and having all the other good qualities of the first hybrids. The variety we now figure, *Rhododendron Princess of Wales*, is one of this second race of hybrids, and one of the most beautiful of them all, the colour being a peculiarly soft but brilliant tint of rose-pink, which is set off by contrast with the pure white of the throat and tube. The foliage is similar to that of the other hybrids of like origin. This variety has been certificated by the Royal Horticultural Society and also by the Royal Botanic Society."—(*Flor. and Pom.* 3 s., p. 3.)

CHAPTERS ON INSECTS FOR GARDENERS.

No. 16.

PASSING to the butterflies, the Purple Emperor claims a place of honour; to hunt it in Oak copses with a pole of unwieldy length is a game delightful to the entomologist on sultry July days. The remainder of these sluglike caterpillars we call "Satyrs"; popularly the species are "Meadow Butterflies," or "Browns," and shades of this colour do really predominate amongst them. From meadows and lawns they pass to our flower beds, though also, in several instances, displaying a liking for dusty roads, which seems peculiar. Thus the Wall Butterfly (*Pyrraga Egeria*), often pitches on walls or stones, and being a good flier it will pass from garden to garden in succession. Like several of its brethren it has hairy eyes, possibly it sees all the better. Most abundant are the two species called the Meadow Brown (*Eupithele Janira*), in meadows and on commons; and the Large Heath (*E. Tithonus*), which is not by any means confined to heaths, but is an occasional visitant in gardens. Two of these butterflies, the Ringlet (*E. Hyperanthus*), and the Speckled Wood (*Pyrraga Egeria*), have a partiality for shady places, and their caterpillars are found in or near roads feeding on grasses. In all of the Satyrs save the Speckled Wood there appears to be only one emergence of butterflies each year, though the whole brood does not come out at once, since we may observe specimens on the wing through as long a period as six weeks or more in some summers. Various grasses afford food to all the caterpillars which hibernate, feeding-up in April and May. None of these species are in any way harmful.

We have now reached the second division of the "Exposers," and here we find the pupa is invariably "girted"—that is, a narrow or broadish belt of silk is passed round the middle, securing it to the surface on which it rests. The butterflies have also six perfect legs. The bulk of the butterflies in this division belong to the first group or section of the two it contains, being with only one or two exceptions insects of small size, and distinguished by having larvæ woodlouse-shaped. The back of one of these caterpillars usually rises into a ridge, the figure altogether is "pudgy" while it clings so closely to the leaf or twig that the head and legs are not to be seen unless it be forcibly moved. Feeding frequently on low plants, caterpillars small in size and much of the hue of the plants they feed upon, are difficult to find; several, indeed, are still unknown in England, common though the butterflies may be. Fortunately none of these caterpillars are injurious. At the head of the list appear the Hairstreaks, of the genus *Thecla*, mostly rapid fliers, fond of sporting in the air a dozen or more feet from the ground. One species (*T. Rubi*), it appears must be singular in habit, if as an entomologist asserts, it has the power of rendering itself invisible. Of course anything may become invisible when it is too far off for you to see it, but if I rightly understand his statement, he means to say that the butterfly by some manoeuvre manages to be close to you and yet prevent your seeing it. Conjurers ought really to look after this insect, as some specimens might be trained to be useful. Seldom do any of these visit gardens, but flowers,

especially Bramble blossom, much delight them, from which they can be swept off with a cautious stroke of the net.

The lively common Copper (*Polymnatus Phleas*) may be seen on various days in the summer along garden walks, sometimes engaged in a mimic conflict with a specimen of the as common Blue butterfly called *Lycæus icarus*, both having a tolerably quick and discursive flight, though the honey of flowers offers some attraction to them. Of the little Copper there seem to be three flights in the year. The Azure Blue (*Lycæus argiolus*) is another Blue likely to be seen near shrubberies, as the caterpillar feeds on the Ivy or Holly. Other Blues, of which we have seven or eight species (in some, however, the blue being replaced by brown, especially in the females), make the rural scene in summer more agreeable to the stroller; the larvæ feeding in a modest way such plants as *Trefoils* and *Velches*.

The second section of the butterflies with girted pupæ comprehends those species which in every season do a certain amount of damage, chiefly in the kitchen garden. Their caterpillars are cylindrical, with the head and legs distinctly visible, and the body is sprinkled with a few hairs. The Whites at once occur to us as illustrations of the group, but, in fact, from only two have we anything to apprehend. Perhaps the Large White (*Pieris brassicæ*) is on the whole the more injurious species, though the Small White (*P. rapæ*) is less limited in its choice of food plants, the caterpillars showing themselves in flower beds on the *Nasturtium* and other Crucifers, on *Tropæolum* and *Mignonette*. Of these butterflies there are evidently several broods during a season. The Green-veined (*P. napi*), on the testimony of the late Edward Newman, does not resort to cultivated plants, nor does the Wood White (*Leucophasia sinapis*), a rather local insect. Conspicuous species in this group are the *Brimstone*, the *Clouded Yellow*, and that rare lover of fens, the *Swallow-tail*, while the pretty *Orange-tip*, near akin to the Whites, appears for a week or two in spring even in the vicinity of London.

Lastly, with brief mention we dismiss the "Concealers," representing a very large foreign group of butterflies. Our six British species are known by the name of *Skippers*, in science the *Hesperia*. The most conspicuous species is the Large Skipper (*H. sylvanæ*), and as it goes from flower to flower in a sluggish way unless alarmed, it reminds us of a moth rather than a butterfly; and in all the *Skippers* when settled the wings are raised above the body, moth fashion.—J. R. S. C.

REVIEW.

The Cactus and other Tropical Succulents. By H. ALLNUTT, 200, Fleet Street.

THIS is a neatly-bound and well-printed little compilation of 130 pages. It appears that Mr. Allnutt made himself a plant case 3 feet long, 22 inches wide, 24 inches high at the back, and 12 at the front. The lower portion is of wood; the remainder glass. A zinc tray covers the bottom of the case, and above this tray a miniature stage of six shelves is formed for the plants. In this tiny greenhouse, which is placed on a table near the window of his living room, the owner has contrived to arrange about sixty tiny plants of *Cacti* and other succulents. These have given him much pleasure, and he has conceived that a brief account of them would stimulate other amateurs to have recourse to the same mode of making their dwellings interesting, and grow these quaint and easily-managed plants. The remaining portion of the book, and by far the most valuable, is made up of extracts (duly acknowledged) from "London's Encyclopædia of Plants," the writings of Mr. Jackson of Kew, Mr. Croucher of Hammersmith, and other growers of small and curious plants. These extracts stamp the book with an authority which it could not otherwise possess, and render it worthy of being recommended to the notice of amateurs and others who are interested in a family of interesting plants. Several of the species are illustrated in a manner sufficient to show their peculiar characteristics. To give quotations would be the extracting of extracted matter.

BARBAROSSA GRAPE.

IN compliance with the request of "J. W." on page 53 I submit my experience. I have two rods of Black *Barbarossa* growing in a house with *Muscats*, *Gros Colman*, and *Lady Downe's*. I have had bunches of Black *Barbarossa* this season 18 inches long, 13 inches across, and weighing from 4 to 5 lbs. each. The berries were as black as elces; and the flavour,

though not equal to that of the Black Hamburgh, was considered by my employer and his friends to be good. This is a useful late Grape when grown with Muscats, being, like Gros Colman, much improved in flavour by being grown in a warm house. I have just cut the last bunch of Barbarossa as fresh as in the month of July. I had some last season until April quite fresh and good.—S. TAYLOR, *Castlecroft*.

TEA-SCENTED ROSES AT LEEK.

I beg to thank "WILD SAVAGE" for his instructions as to the cultivation of Tea Roses in this locality (see page 58).

Doubtless a good deal might be done by selecting Tea Roses for localities, and if growers would kindly furnish lists of varieties which thrive best in their neighbourhood there ought to be a hope of securing a good collection for most districts.

Roses are mostly chosen from those arranged on exhibition tables. Lovers of these flowers go round, note book in hand, making lists of the beauties before them, never taking into account the constitution or hardness of the variety. The plants are ordered, and after their arrival are treated quite differently to what they have been before, and many refuse to live under their widely-changed condition. What is needed is a more intimate knowledge of their constitution and previous culture—with that, and ability and skill to humour the one and imitate the other, there might be a greater chance of successfully cultivating Tea Roses in our northern counties. My advice is to secure plants budded on the seedling Briar, for this, in my opinion, is the best stock for Tea Roses, as upon it they thrive splendidly. I believe from experience that Tea Roses budded on this stock, with protection in winter, may be successfully cultivated out of doors, even in the coldest parts of the kingdom. A little Fern (Bracken) amongst the branches—and a mulch round the roots, with proper and thorough drainage—suffices.

I submit a list of Tea Roses cultivated here. *Souvenir d'Elise* is a shy beauty, but, whether in pot or on walls, dwarfs or standards, is worth all care to produce a single fine flower. *Madame Falcot*, half standard, has been grown three years without any protection whatever in winter; it is beautiful in the bud. *Maria Docher*, standard; *Maria Van Houtte*, always good, and as vigorous as the Hybrid Perpetuals; *Devonensis*, half standard. *Belle de Bordeaux* I have grown three years, and it has never shown a single bloom, so I discarded it altogether. *Marchal Niel* has refused to open out of doors; *Goubault*, the freest and prettiest pink; *Homer*, tipped and wrinkled like Dr. Andry amongst Pelargoniums. To these I would add *Madame Margottin*, one of the best and hardiest of yellows. In *Madame Jules Margottin* and *Souvenir de Paul Neron* we have two charming bouquet Roses of lemon and rosy tints. *Cheshunt Hybrid* was obtained last autumn. This Tea Rose was highly recommended to my worthy employer by the Rev. J. B. M. Camm when in this neighbourhood last July, and I trust its constitution may prove sufficiently strong to brave our severe winters and trying springs.

In conclusion I say, Thoroughly drain your stations before planting your Tea Roses, as I consider this of the greatest importance to the plants, as it enables them to mature their wood much better than they would otherwise.—CIS. ROBERTS, *Highfield Hall, Leek*.

NOTES FROM MY GARDEN IN 1876.—No. 2.

NEXT to Potatoes (indeed, I am not sure whether I ought not to say before them) the vegetable which must and does most bother a gardener is the Pea. Imagine the difficulties a beginner must feel. He wants, say, some half-dozen kinds to secure him a supply; he consults A's catalogue. "Ah! there's a nice lot there, I should like to have some of them." Then he takes up B's, and finds, it may be, a few of those in A's catalogue, but along with them a number of fresh names; he turns to C's list and the same thing is repeated, and so he might go through all the letters of the alphabet, and rise from the perusal a sadder but certainly not a wiser man. Nor is he any way bettered if he writes to ask what are the best sorts. One correspondent praises one list, and a second another list, and so he is at sea again; and no matter what may be the desideratum, modern Peas meet his requirements. Does he want them early? Well, I am not sure but you might find some which ought to be in early in May! Productiveness? He may see photographs where the pods seem to jostle each other so that they hardly have room to hang, and pods so full that by

and-by we may expect to see treble rows. Is quality required? The flavour of some must be so exquisite that the difficulty would be to know when to stop. And, after all, "are we any better than our fathers?" Yes, I unhesitatingly say. We may laugh at the extravagant praises bestowed by the parents on their children and chuff them when we meet, but it seems to me that in all the three qualities I have named—earliness, productiveness, and flavour—we have considerably gained, owing to the perseverance and intelligence of hybridisers and care of selectors (for very many of the new varieties are but selections). There may be further improvement, but it almost seems as if we had reached our limit.

The varieties which I sowed in my small garden last year were *Emerald Gem* (Sutton's), *Early Champion* (Sutton's), *Improved Princess Royal* (Sutton's), *McLean's Best of All* (Sutton's), *Giant Emerald* (Sutton's), *Commander-in-Chief* (Carter's), *Balmoral Castle* (Carter's), *Dr. McLean* (Turner) *Dukes of Edinburgh* (Sutton's). The season was with us a very trying one. I never knew early Peas "so long on the way," owing to the cold dry weather. Midseason varieties did very well, but the later sorts were terribly cut up by mildew. Of some of the above varieties I have already given notes, and those really only new to me were *Commander-in-Chief*, *Balmoral Castle*, and *Dr. McLean*; the others were grown because upon trial they proved so good that I did not care to seek any further for sorts to supersede them. *Commander-in-Chief* is a grand Pea, a wrinkled Marrow, delicious in flavour, pods slightly curved and containing from eight to ten peas; the haulm is vigorous and healthy, and the pods are produced in great profusion. Of *Balmoral Castle* I received but a small quantity for trial. It is a strong and vigorous-growing Pea, evidently of the Supreme type and an improvement on that variety. *Dr. McLean* is in my judgment one of the greatest acquisitions we have had for some time; it is of the *Advancer* type—i.e., a blue wrinkled Marrow, about 4 feet high, vigorous in habit, and astonishingly productive. After you have had one or two pickings of it, it really seems to have as many pods upon it as other Peas which have not been picked at all. The pods are well filled, and the flavour (as it becomes a Pea named after a raiser who made it the one grand point) most excellent. Mr. Turner has been again fortunate in securing a prize of no ordinary value. The Pea which withstood with me the drought best was *Sutton's Duchess of Edinburgh*. My idea that we have, perhaps, reached our limit in Peas is borne out by the fact that there are very few new sorts announced; but many persons hold the theory (which to me seems perfectly tenable) that varieties deteriorate, and that hence we may look for new varieties to take the place of those found to have deteriorated. I believe, for example, *Little Gem* does not by any means rank as high as it did, so that we may expect to find some from time to time replacing varieties now highly valued.

I do not think that in other vegetables I had anything remarkable for novelty, with, perhaps, the exception of *Carter's Heartwell Early Marrow Cabbage*. It is a very close mild-flavoured variety, and succeeds equally well for spring or autumn use. My soil is a good friable garden loam, the situation warm and sheltered, and it may be perhaps of interest to say what varieties of vegetables I have found to do well with me.

Beans (Dwarf).—Canadian Wonder (a wonderful cropper), *Polly's Prolific*, and *White Advancer*. Runner.—Premier; of this I had a remarkable crop.

Broccoli.—Walcheren, Perfection (Sutton), Leamington, and *Champion* (Carter's).

Carrot.—Long Red Surry and *Scaulet Intermediate*.

Cabbage.—*Heartwell Marrow* (Carter's), *Tom Thumb Savoy*, and *Little Pixis ditto*.

Celery.—Sulham Prize and *Sandringham*.

Cucumber.—Duke of Connaught.

Lettuce.—Paris White, Superb White (Sutton's), Tom Thumb (Wheeler), All the Year Round, Commodore Nutt, and *Vilmorin's White*.

Onion.—Improved Reading (Sutton's), Nuneham Park (Cutbush), Long-keeping (James), and The Queen.

Parsley.—Fern-leaved (Carter's). Very pretty foliage, and excellent for garnishing.

Beet and Witloof were a complete failure; not one seedling of either appeared above ground; while *Tomatoes* I have been obliged entirely to discard, the disease having for three or four years destroyed my crop. I have, however, a notion of planting some against a low fence, and seeing whether this

new situation will be any better. I much regret my failure, as Tomatoes are much prized. In conclusion I wish it to be distinctly understood that I only speak of these things as I have found them, and only recommend them for soil and situation like my own. How they may succeed elsewhere I know not.—D., Deal.

MESSRS. BOUTLON & PAUL'S THREE-QUARTER SPAN-ROOF GARDEN FRAME.

This frame for growing Cucumbers, Melons, &c., and for storing plants, with four lights, is 16 feet by 6 feet, is made to give height and convenience. The front is 11 inches high, without the light, 32 inches high at the ridge, and 22 inches high at the back. The front lights can be turned back on to the lights behind, and back lights turned on to the front lights, giving access to all the plants inside. The frames are made of the best red deal, sides and ends 1½ inch thick 2-inch lights; all are painted three times, and glazed with 21-oz.

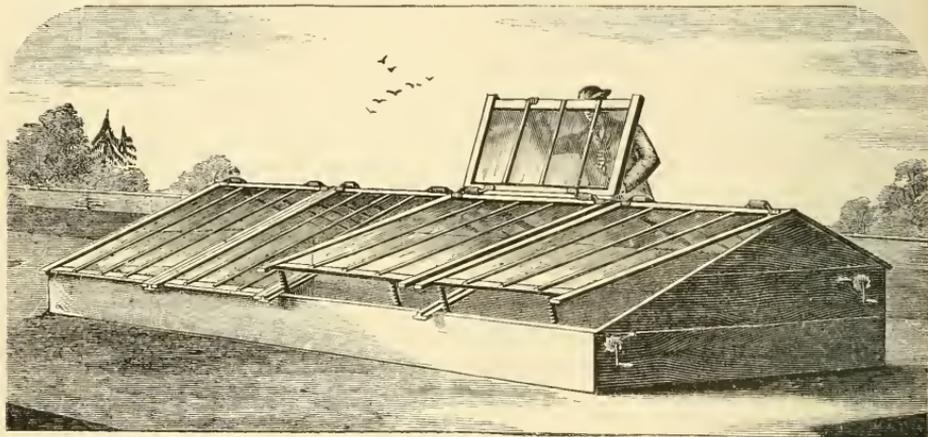

Fig. 17.

sheet glass. The illustration shows the lights to open with gearing. Any of the lights can be lifted up when required without altering the other lights. The back and front gearing works separately.

Only a glance is needed to satisfy that this is a highly useful frame. It is recommended for "storing" plants, but it will not only protect but will aid in growing to perfection during the summer months many plants which are required for indoor decoration. Such plants as Chrysanthemums in their early stages, Primulas, Cinerarias, Calceolarias, Geraniums, Fuchsias, Balsams, Celosias, and many others can be grown much better in frames during the summer months, when sufficient height is afforded, than they can be in houses. By judicious ventilation, early closing, and damping, a genial stove temperature may be provided in a frame during the three principal summer months, and then such plants as Poinsettias, Achimenes, and Gloxinias may be provided for furnishing the more ornamental plant structures. During the winter light roomy frames are very valuable for protecting half-hardy flowering plants and vegetables. Frames are, in fact, indispensable in every garden where protective aids are needed, and they are the gardener's best friends.—W.

MUSCAT GRAPES AND RED SPIDER.

Do Muscats require so much heat as is generally supposed? My reason for asking the question is, that I witnessed a few years ago a large house of Muscats in a very bad state with red spider. The cause of this was said to have been insufficient heating power. Now, in my opinion that was not the sole cause. My reason for thinking that a too low temperature was not the cause of the red spider is this—that I have

been in the habit of growing Muscat of Alexandria and other Muscats in a mixed house for many years, and in a lower night temperature than is generally adopted. Indeed, I may say that throughout the growing season the house I allude to has been kept on an average (during the night) 8° lower than what is advised by many eminent Vine-growers, and I have never been troubled with red spider on the Muscats.

My belief is, that Muscats require more moisture than many other Grapes, especially in the atmosphere. If a Vine border has been allowed to become very dry in winter, or when the Vines were at rest, it will be no easy matter to soak that border in a manner suitable for future requirements. Moisture, it is true, may be applied to the border, but not prepared in the best manner possible as food for the Vine. Anyone who has used manure water must be aware that it is greatly improved by standing, say, two months before using, hence my reason for advocating a good soaking of manure water while the Vines are at rest. The time that intervenes before the Vines are in growth is not best, but is employed as it were preparing food for effective appropriation in due time. Many

are in the habit of never watering their Vine borders from the time the Grapes commence colouring until the Vines are again started in the spring—a much more likely cause of red spider than a too low temperature.

In growing Grapes why do we ignore the teaching of Dame Nature? She is a good guide in these matters, and it is well known that soil in winter is much heavier and carries more moisture than at any other season of the year, and yet many Vine-growers act the very reverse of that, keeping their borders so dry that cracks running in all directions may have been seen in them. Surely that could not be good for the Vines the following season. The soil may contain all necessary ingredients, but water must be present to prepare them for appropriation by the Vines. Inattention to a due supply of water at all seasons has no doubt been the cause of much annoyance with red spider. I have always found great benefits to accrue from liberal mulchings to all fruit trees in winter, and I see no reason why Vines should be starved and red spider encouraged by a deficiency of water at any season of the year.—J. DICKSON.

EARLY WRITERS ON ENGLISH GARDENING.

No. 27.

SIR JAMES EDWARD SMITH, M.D.

NORWICH has for many years been noted for being the birth-place of distinguished botanists and horticulturists; we need only instance within the present century Sir W. Hooker, Dr. Lindley, and the subject of our present illustration.

On the 17th of March, 1823, died at his house in Sarrey Street, in his native city of Norwich, aged sixty-eight, Sir James Edward Smith, M.D., F.R.S., Member of the Academies

of Stockholm, Upsal, Turin, Lisbon, Philadelphia, New York, &c., the Imperial Acad. Naturæ Curiosorum, and the Royal Academy of Sciences at Paris, Honorary Member of the Horticultural Societies of London and Chelmsford, and the first President of the Linnæan Society.

He was the son of a respectable dealer in the woollen trade at Norwich, where he was born December 2nd, 1759, and where he was educated for trade, but changing his plans of life he went to Edinburgh in 1780 to pursue the study of medicine. He had previously attached himself to botany and natural history, and at Edinburgh obtained the gold medal given to the best proficient in botany at that university.

Upon removing to London to perfect his professional knowledge he became acquainted with Sir Joseph Banks, that eminent patron of natural science and of all its ardent admirers, upon whose recommendation he purchased in 1784 the celebrated Linnæan collection, comprising the epistolary correspondence of the great Linnæus and his son, together with everything that belonged to those eminent men relating to natural history or medicine. So highly was this collection esteemed, that the King of Sweden, hearing it was sold, actually sent off a ship to bring back the vessel which contained it; but fortunately for the interests of science the precious loading arrived in England before the vessel could be overtaken.

From that period the life of Mr. Smith was devoted to the ardent pursuit of the science, and his numerous works will constitute a perpetual monument of that fame which no living author more duly merited or more justly obtained.

Having purchased the Linnæan collection and settled in London as a man of acknowledged science in the year 1786, he graduated as a physician at Leyden, and in that and the following year he visited most of the classical and celebrated places of France and Italy. The account of these travels was published in 1793 under the title of "A Sketch of a Tour on the Continent," in three vols. 8vo., a work which at once raised the subject of our memoir into the first class of literary society. Upon his return to London, Dr. Smith, in conjunction with his friend Dr. Goodenough, Lord Bishop of Carlisle, who was one of the original Vice-Presidents, and Thomas Marsham, Esq., who became Treasurer, set about establishing the Linnæan Society, of which Dr. Smith was the original President, and to which distinguished office he was annually and unanimously chosen from that period to the time of his death.

In February, 1788, a few friends met together at the Doctor's house at Chelsea, among whom were Dr. Goodenough, Messrs. Marsham, Lightfoot, Latham, and Dryander. It was at this time agreed that a Natural History Society might be formed on a more extensive scale, and that the new institution might with propriety bear the name of Linnæan after that of the great Swedish naturalist.

At the end of the month a meeting was held at the Marlborough coffee house, the rules fixed and printed the 18th of March following. After this proceeding other members were chosen by ballot, and Sir J. Banks, the Earl of Gainsborough, and the Duc de Noailles made honorary members.

The first meeting was held April 8th, 1788, when "An Introductory Discourse on the Rise and Progress of Natural History" was read by the President. This forms the first article in the "Transactions of the Linnæan Society."

In 1792 Dr. Smith was invited to give some instructions in his favourite science to the Queen and the Princesses at their rural and elegant retreat of Frogmore near Windsor, and how well he was calculated for such an appointment, those who have derived delight and improvement from his lectures at the Royal Institution, at Liverpool, at Bristol, &c., can amply attest.

In the following year he retired from London to reside in his native city, and with occasional visits to the metropolis, where he had a very numerous circle of scientific friends, as well as an extensive acquaintance in the highest ranks of society, to whom he was warmly attached, and by whom he was reciprocally esteemed, Norwich became his constant residence.

In 1814 Dr. Smith received the honour of knighthood at the hands of the Prince Regent, and who had become patron of the Linnæan Society.

The Horticultural Society was pleased to enrol the name of Sir James Edward Smith as one of its honorary members in conjunction with those of the Duke of York, Prince Leopold of Saxe Coburg, and Sir Humphry Davy.

The health of Sir James Edward Smith had been for some time declining, but pursuing the even tenour of his scientific pursuits, and blessed with every comfort which a congenial union can afford, his time glided on without the slightest re-

laxation of ardour in his botanical pursuits, while his latest and even his unfinished works attest there was no diminution either of his zeal or his success in affording information. Although none of his friends could be altogether unprepared for the melancholy event, still the decease of Sir James was somewhat sudden. The feebleness of his frame seemed to have in some degree recovered a little of its former tone during the last week of his existence, so that he was enabled to pursue his accustomed labours, and even to enjoy the exercise of taking a walk without any great fatigue. He was attacked, however, on Saturday, March 15th, with such an alarming degree of debility as almost immediately to extinguish the hopes of his recovery. Under this attack he gradually sunk.

Fig. 18.—Sir James Edward Smith.

Among the numerous works of which Sir James E. Smith was the author it may be desirable here to point out one or two perhaps besides his "Tour," as those upon which his fame was in a great measure reared, and upon which it may be said to be permanently established. Of these "English Botany" is entitled to the first consideration, as containing a description and a coloured figure of every plant known to be indigenous. This work consists of thirty-six octavo vols., and contains 2592 figures of British plants.

It is a curious but a melancholy coincidence that on the very day he entered his library for the last time, the packet containing the fourth volume of his "English Flora" reached him, and he had the gratification of witnessing the completion of a work upon which his friends have frequently heard him express an opinion that it was the one which would eventually redound most to the estimation of his knowledge as a botanist and his credit as an author. This work is dedicated to Sir T. G. Cullum, for fifty years the intimate friend of the deceased.

The productions of Sir J. E. Smith, as an author, during the long space of forty-two years, filled a multitude of volumes, besides tracts and contributions to scientific journals. Besides those already noticed he was the author of amongst others the following distinct publications:—*Dissertatio quædam de Generatione completens*, Leyden, 1786; *Dissertatio on the Sexes of Plants*, from the Latin of Linnæus, Lond., 1786; *Plantarum Icones hæcenus ineditæ, plerumque ad Plantas in Herbario Linnæano conservatas delineatæ*, Fascic. i. 1789, ii. 1790, iii. 1792; *Reliquiæ Rudbeckianæ*, &c., Lond., 1789; *Spicilegium Botanicum*, Fascic. i. and ii., 1792; *Linneæi Flora Laponica*, 1792; *Specimen of Botany in New Holland*, 1793; *Icones pictæ Plantarum rariorum*, &c., 1793; *Natural History of the rarer Lepidopterous Insects of Georgia*, 1797; *Tracts relating to Natural History*, 1798; *Flora Britannica cum notis J. J. Römer*, 1800-1804; *Compendium Floræ Bri-*

tannice, 1800; In Usum Floræ Germanicæ, 1801; Introduction to Physiological and Systematical Botany, 1807. Sir J. E. Smith added to the characters in the two following works of Dr. Sibthorpe: Flora Græca, 1808, and Flora Græca Prodromus, 1808; Tour to Hafod, the seat of T. Johns, Esq., 1810; Læchies Laponnica, or a Tour in Lapland, from the MS. Journal of Linnæus, 1811.

In 1821 Sir James Smith selected from his copious MS. stores two volumes of the "Correspondence of Linnæus with eminent Naturalists." These volumes abound with particulars interesting to all literary men, but especially so to naturalists, and we know it was the intention of Sir James Smith to have favoured the public with a continuation had the success of the first two volumes answered his just expectations. But naturalists are by no means all readers; their studies are rather in the book of Nature than the book of the author. They would not, however, be less fitted for their pursuits if they were more accustomed to add past experience to modern practice by the perusal of works similar to that now noticed.

Sir J. Smith contributed to the Philosophical Transactions a paper on the "Irritability of Vegetables," 1788. His papers in the Transactions of the Linnæan Society are too numerous to be here particularised, as will be seen by reference to the contents of the Society's volumes. He also contributed to Nicholson's Journal, vol. xxii. an "Inquiry into the Structure of Seeds, and especially into the true nature of that part called by Gærtner the Vitellus."

Sir James was a gardener as well as botanist, as is testified by his contributions to the Transactions of the Royal Horticultural Society.

In 1796 Dr. Smith was married to the only daughter of the late Robert Reeve, Esq., of Lowestoft, Suffolk. Lady Smith died on the 3rd inst. at Lowestoft; had she lived about three months longer she would have completed her 104th year. In a case so remarkable as that of Lady Smith it is right to give the evidence of age in full. Here is an extract from the parish register:—P. 393. Christenings in Lowestoft, A.D. 1773. May 12, Pleasance, daughter of Robert and Pleasance Reeve. (Signed) JOHN ANNOV, Vicar." And in the family Bible is following the following entry made by the father:—"11th May, 1773.—The said Pleasance was delivered of a daughter about one in the afternoon, and [she] was baptised by the name of Pleasance." Lady Smith was born two years before the outbreak of the American War, sixteen years before the fall of the Bastille. At the age of twenty-three she was married to Sir James Edward Smith, who was then a young physician of limited means. He found in his young wife a helpmate who took the deepest interest in his pursuits, and their house at Norwich became the centre of the literary and scientific society which then distinguished that ancient city. Lady Smith, after thirty-two years of wedlock, lived in widowhood for nearly half a century; for twenty-eight of those years she resided in the house built by her father in the High Street of Lowestoft. She had a constitution without a blemish, she hardly knew what illness was till within the last two or three years, she had preserved almost all her teeth, and her eyesight was good enough to enable her to read reports of speeches in *The Times*. Her hearing remained almost unimpaired to the very end. To the time when her eyesight began to fail her handwriting was of that clear and beautiful kind which in these days is seldom seen. Even when her eyes grew dim she continued to write letters to those she loved, and though the lines disclosed the difficulty she had in carrying her pen evenly along the paper, the thoughts and language showed no decay of vigour in her mind.

Lady Smith, upon the occasion of obtaining the centenary anniversary of her birth, gave a dinner to all the aged poor in the neighbourhood, and on the same occasion received from the Queen a copy of "Our Life in the Highlands," with the following inscription in Her Majesty's own writing:—"From Victoria R. to her friend, Lady Smith, on her birthday." The deceased had long been accustomed to pursue literary and scientific matters, and nothing gave her more satisfaction than to be kept abreast of *The Times* with information on such topics.—(Various.)

Our portrait is copied from an early one painted by Sir Joshua Reynolds.

GARIBALDI STRAWBERRY.

I RAISED Garibaldi about twenty years ago, it being the only one selected from several hundreds of seedlings, the seed

of which was gathered principally from Elton Pine and Keens' Seedling. It was sent out by myself in the year 1864. Two or three years previous to that date I foolishly let a gentleman's gardener have some of the plants to test, and, contrary to promise, he distributed them amongst a number of his friends, which consequently disheartened me from bringing it prominently before the public until the year 1866.

In conclusion I have to thank Mr. Thomson for his graphic description of Garibaldi (see *Journal of Horticulture* for November 30th, page 367), which I can only confirm.—THOMAS ARMSTRONG, Nurseryman, Moorville, near Carlisle.

ASPECTS OF NATURE—JANUARY.

"Then came old January, wrapped well
In many veils to keep the cold away;
Yet he quake and quiver like to quail,
And blow his nayles to warn thou if he may,
For they were numbed with holding all the day
A hatchet keen, with which he felled wood,
And from the trees did lop the needless spray."

WIND and rain do indeed blow in the face of January, and have this season quite replaced the frost and snow which are in general characteristic of the month; yet whatever the weather there are certain signs and evidences that winter's torpidity is over. "Nature eva in her sleep is never still." The bright rays of the sun penetrating into sheltered places discover to our view many early plants perking-up through the brown earth and pushing-out green shoots to meet the sun's inviting beams. Most conspicuous and earliest of the wild flowers of the year, the Winter Aconite appears like spots of gold on banks and hedgerows, seeming to be giving back from the still brown bosom of mother earth the bright rays of light stored-up from the stray glimpses of the winter sun; but even the Winter Aconite comes not to us more early than January's own offspring, the Snowdrop, with its pure, pale, pendulous petals, which if not originally indigenous to our woods, has become a true wildling in many places.

In sheltered copes and twining amongst the protecting branches of the Quickset hedge, the wild Honeysuckle may be seen even at this early season putting forth small green leaf buds at every joint along its slender stem. Beneath the warmth and shelter of the withered leaves which strew the wood and copse, the brilliant green of the Primrose plants is hid; but such has been the mildness of the past few months that in many places in our southern counties Primroses are in flower, not, perhaps, the fully-expanded delicately fragrant blossoms that smile in the face of the strong March sun, but sweet flowers nevertheless that are welcome to us for their own dear sake, and doubly welcome as a promise of the beauties that are soon to come. The Hazel hangs out its graceful tassell-like yellow catkins before the month is over, and soon the troops of boys and girls will be peering about every branch to discover the pretty scarlet miniature tufts that give promise of the autumn store of nuts. Already the birds appear to twitter with a blither note as though in hopeful anticipation of pleasures to come, while as yet they have known none of the miseries of snow-covered or hard frozen-up soil. The tiny Chickweed has offered them a constant if simple banquet; nor has it needed much search to discover numerous plants of the homely Groundsel, which puts forth a few flowers in greeting to every fine day. The Chickweed is small and insignificant in appearance, yet three hundred years ago it was noticed and commented on by old Gerard, and thus described by him—"The common Chickweed," said he, in his quaint style, "rises up with stalks a cubit high, and sometimes higher, yet ofttimes she almost creepeth upon the ground. A great many stalks spring from one root, long, and round, and slender, full of joints, with a couple of leaves growing out of every knot or joint, of a light green colour. The stalks are something cleare, and as it were transparent or thorow-shining, and about the joints they be oftentimes of a very light red colour, as be those of Pellitorie of the Wall; the floures be whitish on the top, like the floures of Stichtwort, but yet lesser, in whose places succeed long knops, but not great, wherein the seed is contained." The seeds which now are greedily devoured by our little birds, were not less relished by the songsters of the field in the reign of Henry VIII., for the same writer tells us that little birds in cages, especially linnets, are refreshed with the seed of the Chickweed, "when they loathe their meat."

Our list of January flowers is almost exhausted. One hundred years ago Stratton gave a list of only six as truly belong-

ing to the month, and some botanists call the Snowdrop the Fair Maid of February, and place the Daisy amid the manifold blossoms of March; but the Daisy, like the Chickweed, is an offering of every month of the year. It enamels the meadows by thousands in spring, but does not disdain to show its pretty face here and there even during the present wintry weather, unless the snow falls thick upon the ground, or frost binds-up the earth tight in its icy fingers. At such times when

"The cherished fields
Put on their winter-robe of purest white
The brightness all, save where the new snow melts
Along the mazy current. Low the woods
Bow their bow head; and ere the leopold sun,
Faint from the west, emits his evening ray,
Earth's universal face, deep hid and chill,
Is one wild dazzling waste that buries wide
The works of man."

Then, indeed, we look for even the hardiest and commonest wild flowers in vain; but no sooner does the sun shine and

"Shifting gales with milder influence blow,
Cloud o'er the skies, and melt the falling snow,
The soften'd earth with fertile moisture teems,
And, freed from icy bonds, down rush the swelling streams,"

than we see many evidences of renewed life in trees and plants. The wee modest crimson-tipped flower perks up its little head from the surrounding dark green leaves, and we see

"few frail friendly plants,
Withstand all storms, and 'e'en in this dull month
Look green and cheerful."

But even these few of Flora's train, and the hardy insects such as the winter gnats and a few venturesome beetles that creep from their winter quarters at the invitation of a warm bright day, make nature more cheerful, and prepare us for the time when spring

"Shall rise renewed from winter's sleep,
And bid the flowers re-bloom."

—T. S. J.

APPLE ELECTION.

As a grower of nearly a hundred different kinds of Apples, I have watched with great interest the result of the proposition of our friend Mr. Robeson as to an Apple election. I was afraid the subject had dropped until I saw the letter of "AMATEUR" in this week's paper. I quite agree with him in his decision, but think that three sorts of summer Apples are sufficient for our purpose, as so many other fruits clash with the summer Apples.

I shall be pleased to carry out the election if your readers in the Apple-growing counties of England will kindly forward me the names of fifteen dessert and fifteen kitchen Apples as a succession. I have sent the names of fifteen of each kind—not, perhaps, what I should entirely choose myself, but as showing the different varieties; some are good croppers and others of good flavour. Those I should advise to growers who have limited space I have marked with an asterisk. This small list may satisfy us for our first attempt, perhaps another year we may increase our list; as it is, I have no doubt the number will reach a hundred sorts.—LEWIS A. KILLICK, Mount Pleasant, Langley, Maidstone.

P.S.—If my idea is carried out, I shall be pleased to receive any intelligence on Apples or Apple trees from my correspondents, which when the election is over I will endeavour to put into shape for your readers.

DESSERT.

KITCHEN.

Joaneting	Manck's Codlin

*Sturmer Pippin	French Crab

POINSETTIA PULCHERRIMA PLENISSIMA.

We are all more or less anxious to publish the success that may have attended our efforts in growing any new plant or vegetable; but I think much information may be given and received if growers would state their failures and mishaps when

they occur, and I fear there is none of us who do not meet with them occasionally. The above-named plant was sent out last season by the Messrs. Veitch, and it was spoken of as being grand, not only by the vendors, but by good gardeners who had been supplied with plants for trial, and it was generally described as being far superior to the old scarlet Poinsettia. In the spring I had a small plant of the new variety sent to me from London, a neighbouring gardener also receiving a plant at the same time. I potted mine in the same kind of soil and gave it the same treatment as my old Poinsettias, but I was disappointed with the new one. It was paler in colour and very little more double than the other, and not so large. Some of my old Poinsettias measured 15 inches across the bracts, while the new one did not exceed 10 inches, and my friend was rewarded much in the same way as myself. Will someone who has been more successful state their opinion and mode of treatment? as by so doing they will have the thanks of others as well as myself.—S. TAYLOR, *Castlecroft*.

CULTURE OF PRIMULA SINENSIS.

At the Darlington Gardeners' Institute a paper on the cultivation of the *Primula sinensis* was read by Mr. Wrather of Greencroft West. He observed—The *Primula sinensis*, or Chinese Primrose, is one of our favourite plants for blooming either in autumn, winter, or spring. It is alike suitable for greenhouse, conservatory, or house decoration, and is very valuable for cut flowers. The cultivation of the *Primula* is simple and easy, and will amply repay the attention given to its cultivation, either by gentlemen's gardeners or amateurs. It is suitable for those amateurs who possess a greenhouse with artificial heat, and it is very desirable that they should grow such a floral gem, but it did not appear to be a plant sufficiently attended to or grown so extensively as it deserved to be.

Plants may be had in bloom from October to May by successive sowings from the middle of March to the end of May or early June. Mr. Wrather said he generally sowed in pans in a compost of turf, leaf soil, and sand, with good drainage of crocks covered with the roughest leaf soil. The pans are then filled within half an inch of the top with the prepared compost pressed moderately firm. The seed is sown evenly on the surface, a mere dusting of silver sand or sandy soil is spread over it, great care being taken not to cover it too deeply, as one of the principal causes of failure in raising from seed arises from not observing the latter directions. Another important matter is the watering, and dipping the pans very gently overhead into the water he had found the best plan. For the earliest-sown a temperature from 55° to 60° was recommended, with a slight bottom heat if at the command of the grower. A piece of glass placed on the pans would hasten the germination of the seeds. From the time of sowing to that of potting from six to eight weeks elapse. His first lot is potted into 3-inch pots about the 13th of May, a compost of turf, leaf soil, with sand and horse droppings from the Mash-room bed being used. The pots are then placed in a pit with a south aspect (but shaded) for ten days or a fortnight and kept close. By the middle of June these plants are ready to shift; the same compost, with the addition of cow manure, being again used. The later sowings are ready for shifting into their blooming pots about the middle of August or the beginning of September. When the plants are wanted for the decoration of the sitting-room or hall 5-inch pots are large enough, as they are often placed in vases; but for greenhouse or conservatory 6 or 7-inch pots may be better, as the larger the pot the greater chance of good plants and flowers.

Care must be taken in potting to keep the collar of the plants well up in order to prevent damping-off, which they are apt to do. From this time till wanted for the house or conservatory they should stand in pits or frames with a south aspect, shaded from the sun either by whitewashing the glass or otherwise until the latter part of August. They should be placed on ashes to prevent worms entering the pots. Some practical cultivators recommend a north or east aspect in summer, and doubtless they may be safely grown in either from June to August. In September the earliest ought to have a top-dressing of cow manure and turf. This will cause the flower spikes to stand well above the foliage, produce larger flowers, and make much handsomer plants. When the pots become matted or full of roots liquid manure should be given, at first cautiously and weak. Some cultivators recommend guano, he preferred something less heating and exciting. He used with success liquid manure prepared from cow dung, and

believed it to be the best. Whatever liquid was used it ought to be clear, and should not be allowed to touch the foliage. Unless seed be wanted the pods should not be allowed to remain on the plants.

CARROT CULTURE.

On page 60 "B. G." records a plan by which he secured a supply of Carrots free from the maggot, and asks others to give their experience. In compliance with his request I shall state briefly the method I adopted last season, which proved successful; for here, in common with many other places, it is impossible in ordinary circumstances to grow Carrots in the garden free from that abominable pest the maggot.

Last season, before cropping time, I procured a quantity of peat dross—the refuse of the peat stack, that material being extensively used as fuel in this locality. This I spread 6 inches deep over part of the ground intended for Carrots. I then gave it a slight fork-over, only mixing a very little of the original soil with the peat, the ground having been previously trenched and well pulverised. On this I sowed the Carrot seeds in the usual way, and the result was a crop of perfectly sound and healthy roots, and quite free from the maggot. The sorts grown were Altrincham (select) and James's Intermediate, and the time of sowing was about the end of April.

I have no doubt ordinary peat or leaf soil would answer the purpose as well as the dross. On the portion of ground that had not the peat dressing the maggot did its usual work.—JNO. HARDIE.

I HAVE grown Carrots successfully for the last twenty years. First of all I have the land well drained; next I have it trenched 18 inches deep to provide depth for the roots to grow straight down without being forked. In February or March, according to the weather, I give the ground a dressing of quicklime, one bushel to each pole of ground in the kitchen garden, and I give one ton to each 20 poles of arable land when the Carrots are to be sown in the field. The ground requires forking over and raking in dry weather in the kitchen garden. Ploughing and harrowing answer equally as well in the field. If anything should attack the young Carrots in May they will require to be gently dusted over with a mixture of lime, soot, and wood ashes; and all that is afterwards necessary is thinning the plants and hoeing the ground till the crop is ready to be stored, and that ought to be a month before the frost sets in.—WILLIAM GAIN, *Gardener, Lyneceod.*

P.S.—Those that would grow this useful root
Free from blight and maggots,
Must freely use both lime and soot,
And they will have fine Carrots.

Our garden soil is cold, stiff, and heavy—very unsuitable to the growth of Carrots. I am told for years previous to last season they were invariably injured by the maggot, but last year we had a heavy crop of large clean roots. We sowed James's Intermediate Scarlet as a main crop during the first week of April, on a plot which had been double-dug the previous autumn and heavily manured for the preceding crop. We drew the drills deep, half filled them with wood ashes, sowed the seed, and covered slightly with light dry soil. I have one of your correspondents to thank for my success. I think it was Mr. Abbey who recommended wood ashes to prevent wireworm. I would advise your correspondent "B. G." to give wood ashes a trial.—THOS. COOMBER.

NOTES AND GLEANINGS.

We have received the supplementary programme of the INTERNATIONAL HORTICULTURAL EXHIBITION to be held at Amsterdam from the 12th of April to the 2nd of May. Intending exhibitors must notify their intention to the Secretary-General before the 1st of March. The programme is divided into ten sections.—1, Plants for the stove and temperate house; 2, Greenhouses and conservatory plants; 3, Open-air plants; 4, Arrangements of plants and flowers; 5, Fruits, vegetables, and seeds; 6, Industry as applied to horticulture; 7, Art, as applied to horticulture and botany; 8, Progress; 9, Horticultural science; 10, Awards, medals, and certificates to native and foreign gardeners. Many hundreds of medals, diplomas, and certificates are provided, the value of the medals ranging from upwards of £14 to 8s. Exhibitors have the option of receiving money instead of medals, provided they give a written

notice to that effect on or before March 15th. The sections are divided into several sub-sections, and a great exhibition is anticipated. The programme is signed Hoefft van Velseo, President; J. B. Groenewegen, second Secretary.

In order to afford adequate convenience for expected large importations of plants from his foreign collectors Mr. B. S. WILLIAMS is enlarging his nursery at Holloway and erecting new structures. The general stock of plants now in the nurseries is in superior condition. Amongst the new plants *Arucaria Goldiana* is being largely increased, and a large stock is being established of the new and elegant *Panax laetnatus*. An Australian Fern, *Dennistadia davallioides* Youngii, is elegant and stately, and the fine *Gleichenia rupestris* glaucocens, and *Mendelii*, are very noticeable. Amongst the stately Tree Ferns in the conservatory *Dicksonia Youngii* is growing with great freedom and elegance; and especially attractive amongst the Palms are *Areca lutea* and *Verschaffeltii*, *Kentia australis*, *Stevensonia grandifolia*, a new *Martinezia* with marbled stems, and *Drahea filamentosa*—a pair of fine specimens from California. Many choice Orchids are flowering, including *Laelia Dayii* and *superbiana*, *Odontoglossum*, *Zygopetalum*, and *Cypripedium*; and an extensive importation of *Odontoglossum cirrhosum* and *Oneidium Rogersii* is being established. The hardwooded plants—*Ixoras*, *Camellias*, *Heaths*, &c.—are equally worthy of notice for their health and cleanliness. In "another department" is the magnificent prize of china—timepieces, urns, and candelabra—from the Crown Prince and Princess of Germany, the premier prize of the Cologne Exhibition; another honour of note being the King's gold medal which was awarded at the last Brussels Exhibition.

At the last meeting of the Committee of the NATIONAL ROSE SOCIETY a satisfactory statement as to the progress of the Society both as to funds and members was made by the Secretaries. Amongst the announcements made was one which we are sure will be hailed as a token of success—namely, that Mr. Cranston of Herford had made the munificent offer of a challenge cup of the value of fifty guineas to be competed for by amateurs, the cup to be won in three years: thus, if Mr. A wins it in 1877 and Mr. B in 1878, then only A and B are to compete for it in 1879. The schedule was arranged, and a circular drawn up by the Secretary was approved and ordered to be printed and circulated. It was the opinion of all present that a prosperous future might be safely relied upon.

We have just been informed that the GRAND QUINQUENNIAL HORTICULTURAL EXHIBITION at GREENT will be held in April, 1878. This will no doubt prove equally attractive with those that have for so many years brought together horticulturists from all parts of Europe, and we trust that our national horticulturists will bestir themselves and send such a representation of British horticulture as will do credit to the country.

The Judges in the horticultural department of the Philadelphia International Exhibition, 1876, recommended to the United States Centennial Commission for awards a "very choice collection of NEW AND RARE PLANTS, well grown and in excellent condition after trans-shipment of such delicate articles—an exceedingly creditable display," exhibited by Mr. B. S. Williams; also "a small collection of Filmy and other Ferns," exhibited by the same nurseryman. "A very rare collection of Rhododendrons, Hollies, new and rare Conifers, broad-leaved evergreens of the best kinds for lawn decoration," exhibited by Messrs. Jas. Veitch & Sons, Chelsea; also "an exhibit of evergreen plants, consisting of the best varieties of Rhododendrons, Hollies, *Aucubas*, &c., for fine growth and careful training, and unique in new kinds," shown by the same firm. A medal was also awarded to Mr. W. Bull for "coloured plates of flowers."

The next INTERNATIONAL POTATO SHOW will be held in the gardens of the Royal Horticultural Society some time in September next, and the prize list will probably include a set of the Society's medals. The promoters of this Show offered it to the Society in the first instance, but Lord Bury's Council failed to perceive that South Kensington was the proper place for it.

THE GALLOWAY ROSE SHOW is to be held this year at Newton Stewart, Wigtownshire, on the 17th of July.

THE FLOWER MARKET at COVENT GARDEN is attractive at any period of the year, but especially so during the opening days of spring. Bulbous plants—Tulips, Narcissuses, and Hyacinths

are now offered in large numbers. *Cytisuses* are "coming in," *Callas* are freely represented, and *Azaleas*, small plants with dense heads of flowers, are exceedingly gay. The most effective bouquets are composed of white *Camellias*, *Eucharises*, and *Rose huds*, with a few *Giant Violets* between the larger white flowers, and a veil of *Snowdrops* arranged over the entire bouquet, the "drops" being an inch and more above the other flowers. The fringe as usual is of *Adiantum cuneatum*. The favourite "button-holes" are composed of a cream-coloured *Rose bud*, a single pip of white *Hyacinth*, a spray or two of *Lilies* and *Fern*.

— We are informed that *Messrs. James Veitch & Sons* of Chelsea have obtained by public tender all Mr. Laxton's SEEDLING PEAS and STRAWBERRIES.

— A KENTISH correspondent informs us that the NUT TREES are blossoming with great freedom, and are now quite ornamental from their immense crop of male catkins. These, he says, are coveted for decorative purposes, sprays of them possessing a "sober elegance" when placed in vases that few flowers can equal. The small inconspicuous female blossoms are also plentifully represented, and good crops of nuts are anticipated.

— We have received from *Messrs. Letts & Son* a set of their well-known DIARIES. They are of various sizes, and available for every purpose, from being carried in the waist-coat pocket to being placed on the counting-house desk or study table. Besides the diary they all contain a good almanack, and the larger ones, especially No. 5B, also contain a large amount of valuable commercial information. We can strongly recommend these as being highly useful.

— THE DARLINGTON GARDENERS' INSTITUTE was founded by E. Pease, Esq., brother to the member for South Durham. In addition to a valuable horticultural library he generously gives £50 per annum for its support. The Institute contains, besides the necessary apartments for the librarian, library, reading-room, and smoking-room. Papers are read during the winter months once a fortnight. There is also a fruit and floral meeting held (part of the year) weekly. The reading room is well attended, especially by the young gardeners. E. Pease, Esq., is President.

— We have received from Mr. R. Gilbert, Burghley Gardens, near Stamford, some flowers of DOUBLE PRIMULAS. The individual pips are $1\frac{1}{2}$ inch in diameter, and are perfectly double, every petal also being deeply serrated or "fringed." The flowers are bluish white, some of them being delicately and others more heavily blotched and flaked with rose. The darker types of flowers are rosy carmine, deepening towards the centre, the reverse of the petals being bluish pink. As fringed varieties of double Primulas we have never seen any flowers superior to the example now brought to our notice.

— MR. F. H. FROUD writing to us from the Gardens, Hawley House, Kent, on the MILDNESS OF THE SEASON, states that he has been gathering *Aconites*, *Snowdrops*, *Crocuses*, *Hepaticas*, and other flowers from the open garden during January. He gathered the last *Roses* on January 5th, one a beautiful *Gloire de Dijon*, as good a bloom as he ever cut in summer. It was cut from a plant trained to a west wall rather sheltered. A white *Camellia* planted out of doors with five others also in a sheltered position facing north, is now (February 6th) in flower, and two others are in a very forward state. *Deciduous* and other flowering shrubs are fast bursting into leaf and flower, and bulbs of all kinds are appearing through the ground, and vegetation generally is in a very advanced state.

— We have received a copy of the new and revised edition of Cassell's "Household Guide," and we can testify that the directions and the plates, coloured and plain, justify the statement that it is useful in "every department of practical life."

— WHOEVER wishes for full particulars relative to the colony of Victoria should read Hayer's "Notes on Victoria."

— IN Mr. Burley's, Herford Road Nursery, Bayswater, there is now to be seen a fine specimen of *ASPIDISTRA PUNCTATA*. The *Apidistras* are remarkable for producing their flowers under the soil, where they grow and mature and die—seldom coming to the daylight. The flower of *A. punctata* is purple in colour, has six lobes and six anthers (sessile), and a stigma like that of a Poppy.

— As instances of the MILDNESS OF THE WEATHER AND WINTER IN SOUTH WALES, we recently noticed in the extensive

and beautiful pleasure grounds at Margana Park, Glamorgan-shire, Hawthorn in flower, *Camellias* as standard bushes in the open air with fully expanded blooms, early *Rhododendrons* showing colour, and *Coronilla glauca*, which is generally treated as an inmate of the greenhouse, covered with its yellow flowers in the open border, the first and last-named of these plants having been in bloom since Christmas.

— THE PROGRAMME OF THE ROYAL HORTICULTURAL SOCIETY for the ensuing year will contain a special invitation to local horticultural societies to subscribe, and to receive in return medals of the Royal Horticultural Society for distribution at their local exhibitions, together with the privilege of appointing one of their committee to represent the society at all meetings, &c.

— At the Annual General Meeting of the ROYAL HORTICULTURAL SOCIETY held on the 13th the following candidates were proposed and duly elected Fellows of the Society—viz., Jas. Aldous, Madame Bassano, Mrs. Bentham, Richard Dean, William Hume, H. W. Durant, Col. H. P. Goodenough, Peter Grieve, Mrs. Hargreaves, Dowager Lady Keane, Miss Longman, Mrs. McGarel, R. B. Postans, Jno. C. Quennell, Mrs. Robertson, G. Smith, G. D. Stubbard, G. D. Whatman, Jas. Baily, Col. A. Croll, Robert Drummond, J. D. C. Farrell, Hon. J. T. Pienne, Thos. Lyon, Sir H. St. John Mildmay, Bt., Sir Julian Pauncefote, Mrs. Laurence Peel, T. Francis Rivers, Mrs. Culme Seymour, Viscountess Templeton, Geo. A. H. Tucker, Count Guidoboni Visconti, Robt. Wake, Edward Webb, E. A. Webb, Lieut.-Col. Gould Weston, Mrs. W. Burbury, Hon. Olivia Calthorpe, Mrs. A. Croll, &c.

— On the 27th of January died Mr. WILLIAM MELVILLE, aged sixty-six. He was gardener for thirty years to the Earl of Roseberry, Dalmeny Park near Edinburgh. Mr. Melville was an ardent horticulturist and a keen hybridiser. In his youthful years the Pansy was one of his favourites, and he was one of the first to improve it. In his later years the Brassica family attracted his attention, and he raised the Roseberry and Albert Sprouts also many fine forms of variegated Kale. He was also the raiser of the Champion Muscat Grape, a variety seldom seen now, but when well grown no other of the Black Muscats surpasses it in flavour; the berries are very large, but resemble in colour the Grizzly Frontignan. Mr. Melville resigned his situation in 1869, and received a handsome annuity from Lord Roseberry. He retired to Jersey, where he managed a range of vineries on his own account very successfully at Tynville St. Aubyns, where he died. He was a man of pleasing manners, very fond of entering into conversation with gardeners like-minded with himself. He was the father of fifteen children, whom he educated and trained to good positions in life. Six of his sons follow the profession of gardeners; let us hope that they will emulate the example of their parent, and if they cannot all attain to the same height in their profession as he did, they can deserve success.

— On the 4th inst. Mr. JOHN HARRISON, nurseryman, of Darlington, Seorton, and Catterick, died in his own home at Catterick, at the age of seventy-six. Mr. Harrison stood very high as a Rose-grower, and was well known as a prizetaker at exhibitions. His *Roses* were in request over the kingdom, and he also shone as a cultivator of *Dahlias* and *Hollyhocks*. Mr. Harrison was a native of Yarm, and had been in business at York before he took the Darlington Nursery. Those who were well acquainted with him say that his love of *Roses* dated from a very early age, and he has been known as a practical cultivator of that queen of flowers for sixty years at least.

— AN American paper says the art of MAKING SCARFCROWS should be studied. It is an imaginative bit of work to make an artificial hawk from a big potato and long goose and turkey feathers. The maker can exercise his imitative skill in sticking the feathers into the potato so that they resemble the spread wings and tail of the hawk. It is astonishing what a ferocious-looking bird of prey can be constructed from the above simple materials. It only remains to hang the object from a tall bent pole, and the wind will do the rest. The bird makes swoops and dashes in the most headlong and threatening manner.

— At the last meeting of the LINNÆAN Society a pot of growing WHEAT was exhibited by Mr. R. Irwin Lynch, which had been sown from the grain left in *Polaris Bay*, 81° 38' N., by the American Expedition. The grain had been exposed to the winter frosts, 1872-76, yet the above sample grown at Kew

gave 64 per cent. as capable of germination. A grain of Maize among the Wheat also germinated.

ROYAL HORTICULTURAL SOCIETY.

FEBRUARY 14TH.

At the meeting held on Tuesday the President of the Society acknowledged the aid of the principal nurserymen in rendering the meetings and shows attractive. The contributions had been well merited, and liberal contributions of plants arranged in the conservatory to-day constituted an extensive and beautiful spring exhibition—a good augury that the year is not to be a barren one, and that future gatherings will be worthy of extensive patronage. The display was arranged on tables occupying the entire length of the conservatory; and when we say that the best examples from such sources as those of Messrs. Veitch, Williams, Ball, Turner, Wills, and Osborn, besides those of private growers, were forthcoming, including a large collection of fruit from Leonardlee, the value and character of the show, for show it was, will be understood.

FRUIT COMMITTEE.—Henry Webb, Esq., V.P., in the chair. Mr. Joshua Atkins, gardener to Col. Lloyd Lindsay, sent three very fine bunches of Black Alicante Grapes, which were awarded a cultural commendation. Mr. Harrison Weir, of Weirleigh, Kent, exhibited a dish of Mrs. Pince's Muscat Grapes, which were grown in a house without artificial heat. The flavour was excellent, and the fruit was in fine condition. A cultural commendation was awarded. Messrs. Veitch exhibited two seedling Apples they received from France and Lancaster, but they were not of superior quality. Messrs. Veitch also exhibited a large seedling Pear from Acton, which was not considered of any merit. Mr. Z. Stevens, gardener to the Duke of Sutherland at Trentham, sent a tree of Calville Blanche Apple in a pot laden with fruit. These trees are used for table decoration at Trentham. The fruit was very fine, and, though somewhat past its best, was very good. A cultural commendation was awarded. Messrs. Stuart & Mein of Kelso sent a punnet of the Lily-white Seakale, which is of an uniform bright yellow colour, and not tinged at the points with purple, as the ordinary variety is. It was decided that before an opinion could be formed of its merits it should be grown at Chiswick side by side with the old variety, and when cooked submitted to the Committee. Mr. James Batters, gardener to Mrs. Willis Fleming, Chilworth Manor, Romsey, sent a basket of Snowflake Potatoes grown in 7½-inch pots. A cultural commendation was awarded. Mr. Batters also exhibited a dish of Mushrooms. A couple of specimens of Limes grown at Nettlescombe, Somerset, by Sir Walter Trevelyan, were exhibited by Mr. David Wooster. A very fine collection of Apples and Pears was exhibited by Mr. Sidney Ford, gardener to W. E. Hubbard, Esq., Leonardlee, Hordsham, and the Committee recommended a Davis bronze medal.

The Fruit Committee—having had under their consideration the correspondence in reference to the Grapes exhibited by Mr. Bell of Clive Hoase, Alnwick, before them on December 6th, 1876—desire to place on record their regret that Mr. Bell should have withheld the facts as to the origin of the Grapes, and more particularly draw attention that in his letter to the Committee with the Grapes he stated the parentage was "a cross with Black Morocco, and a seedling raised, I understand, at Wordley," and in his letter of January 25th, 1877, in *Journal of Horticulture*, he affirmed "it is a founding, the parentage and connections of which none can vouch." Had the Committee known at the time of making the award the real facts of the case they would not have recognised the name of Clive Hoase Seedling, and which they now cancel.

FLORAL COMMITTEE.—Mr. E. S. Williams in the chair. Messrs. Veitch exhibited a large group of plants, gorgeous by a collection of nearly a hundred Amaryllids, in colours ranging from rich crimson scarlet to creamy white, some of the petals being tipped, others mottled, and nearly all of great substance and superior merit. A first class certificate was awarded for Princess of Teck, flame scarlet. The Orchids in this collection included Lycaste Skinnerii in several varieties, and *L. cruenta*, highly perfumed; *Lælia pulcherrima alba*, very beautiful; *Angrecum sesquipedale*, with five flowers; *Phalenopsis*; *Odontoglossum* in several species and varieties; the singular *Masdevallia Wallisii* (chimeras), to which a first class certificate was awarded. *Chysis Chelouai*, a fine cross from *C. hevis* and *C. Linnæi*; *Cypripedium*, including *C. Schlimmii album* and *C. Haynaldianum*; *Dendrobium Domini*, and *D. eudochæis*, the latter being a distinct cross between *D. japonicum* and *D. heterocarpum*, a fine plant of *Dendrobium plumaceum*, &c. In the centre of the group a striking lilaceous plant—*Euryclis australis*—commanded much attention. It somewhat resembles an Eucharis, but each flower spike, which is stout and 6 inches in height, is surmounted with a dozen white flowers with yellow stamens. This will be invaluable as a decorative plant, and is almost sure to find its way into most conservatories. The group was fringed with superior Cyclamens and Lilies,

and contained densely bloomed examples of *Rhododendron Early Gem*; also a fine form of *Cydonia* (*Pyrus*) japonica alba, much superior both in the size of the flowers, purity of the petals, and free flowering, to the old white. The new variety was introduced by the late Mr. J. G. Veitch, and must be pronounced an acquisition; a first-class certificate was awarded. Messrs. Veitch also exhibited flowering sprays of the new shrub *Azara microphylla*; *Cornus* variegata, covered with small orange-coloured flowers; and a collection of cut blooms of *Camellias*. A silver-gilt medal was recommended for the collection.

Mr. Ball staged a very commanding group, every plant being choice and in superior condition. The background was composed of *Cycads*, *Eucapharises*, *Draenas*, *Palms*, *Florumams*, &c., at the front of which were Orchids and ornamental-folaged plants. Amongst the Orchids were *Odontoglossum cirrhosum*, *Lycaste Skinnerii* rebella, very rich; *Uropidium Lindenii*, *Odontoglossum Roselii*, *Dendrobium speciosum* and *Wardianum*, *Cypripedium Harrisonianum*, and a bright yellow *Cypripedium*, resembling *C. pubescens*. To one fine plant in this group—*Cycas media latissima*—a first-class certificate was awarded; a similar award also being given for *Croton Mortii*, a bold and stately plant with well-coloured foliage; and a silver medal was recommended for the collection.

Mr. Williams exhibited Orchids, including *Dendrobium nobile* and *Wardianum*, *Lælia superbens*, *Lycaste Skinnerii*, remarkably well bloomed; *Odontoglossum cordatum*, *Zygopetalum crinitum*, and *Cypripedium Dayanum*, insignis, and villosum; also *Palms*, *Cyclamens*, and plants of a splendid strain of *Primula sinensis fimbriata* alba. A vote of thanks was awarded.

Mr. Wills staged a large collection, arranged in a bold free style, which is an agreeable relief to the orthodox formalism of flat smooth groups. The large plants consisted principally of *Palma*, the groundwork being composed of small flowering plants and *Adiantums*, with an irregular fringe of *Ficus repens* and *Isolepis gracilis*. A vote of thanks was awarded.

Messrs. Osborn & Sons, Fulham, exhibited a small collection of choice *Palms* and *Aralias* suitable for table decoration. The plants were remarkably healthy and clean, and meriting and receiving the thanks of the Committee.

Mr. Turner, Slough, exhibited well-bloomed *Camellias*, the old *Douglasii* being conspicuous by its numerous and richly marbled flowers. Fine standard and heavily berried *Acacias*, a standard umbrella-like plant of *Euconymus latifolius* variegatus, and ornamental pyramid *Ivies*. A distinct and excellent group for which a vote of thanks was given. Mr. R. Dean, Ealing, exhibited a collection of *Primroses* (some of them *Polyanthuses*), in pots. A new white, *Virginiana*, *P. altaica*, *Rosy More*, *Brilliant*, and others were very effective. Mr. Dean also exhibited *Victoria Regina* Violet in good condition. Mr. Aldons also staged a compact collection of flowering plants, and both exhibitors received the thanks of the Committee.

Mr. F. Newman, gardener to W. H. Micholl, Esq., Highgate, exhibited a very fine group of Orchids, including upwards of a dozen *Phalenopsis*; *Colax jacobus*, distinct from the purity of its sepals and its heavily blotched petals; *Vanda Cathcarti*, *Miltonia Warszewiczii*, *Odontoglossum triumphantis*, and superior *Dendrobium*, *Wardianum*, *crassinode*, and *lituiflorum*—an extremely fresh and bright collection, for which a silver medal was recommended.

Mr. James, gardener to W. F. Watson, Esq., Redles, staged nearly a hundred *Cyclamens*, excellently grown, and in superior varieties; also a dozen seedling *Cinerarias*, remarkable alike for the vigour of the plants and the high quality of the varieties. A silver medal was worthily recommended for this excellent collection. Messrs. F. & A. Smith, Dulwich, also staged good *Cinerarias*.

Mr. Ollerhead, gardener to Sir Henry Peek, Bart., Wimbledon Hoase, staged a small but very good group of Orchids, *Vandas suavis* and *tricolor*, *Dendrobium Boxallii* with fifty-three flowers, *D. crassinode*, *Phalenopsis*, &c. and received the thanks of the Committee. A similar mark of acknowledgment was made to Mr. Roberts, gardener to W. Terry, Esq., Peterborough Hoase, Fulham, who staged a small collection of Orchids, *Coleogyne cristata* and *Godylersia diolor* being in very good condition.

Sir Trevor Lawrence, Bart., Burford Lodge, Dring, exhibited some choice Orchids, botanical commendations being awarded to *Cestanthum sonna*, distinct and powerfully perfumed; and *Spathoglottis Lobbi*, pale yellow; and a first-class certificate to *Odontoglossum Cervantesii* var. *decorum*, a great improvement on the species. *Miltonia Warszewiczii pallida* in this choice group was very beautiful. A first-class certificate was also awarded for *Calanthe vestita rubra oculata*, very vigorous and fine.

A cultural commendation was awarded to Mr. Denning, gardener to Lord Londesborough, for a densely flowered plant of the Cobweb *Dendrobium*, *Dendrobium teretifolium*; and a botanical certificate for *Masdevallia macrura*, a robust and remarkable species from the State of Columbia. Mr. Lasing, Forest Hill Nurseries, exhibited forced Lilacs; and Mr. Clarke, Twicken-

ham, fine baskets of Cyclamens, and received a vote of thanks. A first-class certificate was awarded to Mr. Edmonds, Hayes Nursery, for Cyclamen persicum album magnificentum—a compact plant, but not a compact name.

Prizes were offered by Messrs. Veitch for Poinsettia pulcherrima plenissima, and were awarded—first to Mr. Orllerhead, and second to Mr. Tubbs gardener to B. W. Smith, Esq., Hampstead. Mr. Orllerhead's specimen was fairly good, but the others were only indifferent.

In addition to the above collectors the conservatory was rendered attractive by a well-grown assortment of flowering plants from the Society's Garden at Chiswick.

DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

HARDY FRUIT GARDEN.

The weather during last week was very fine, and as the borders had an untidy look with the manure dressing on the surface it has been dug in. Pear trees are in a very forward state, and a few weeks of fine weather will cause the buds to burst their scaly coverings. It would be better if the weather was colder, as there is always a great risk in an early-blossoming period.

It is time that nailing was quite finished, as the season is so early, and when the buds are too much advanced they are frequently rubbed off during the operation. All the work ought to be done in a careful manner, and if many decaying branches or any that are badly gummed have to be removed, it may be better to loosen all the branches from the walls and re nail them regularly over the required space. As a rule wall trees are too much crowded with young wood, and when this is the case fine well-coloured fruit cannot be expected. Peach trees are usually left until the last, and after all useless wood has been removed the trees should be washed with strong soapy water if they are infested with any insect pests, taking care not to injure the buds which are now well advanced. Pan-trained trees have usually the weakest and most unsatisfactory growth near the base of the wall, and the growths improve towards the top of the tree. Sometimes it is better to remove the weak under-growths and bring down those nearer the top. This may be done a little every year, and the trees will be kept in better condition thereby. All the main branches ought to be laid into their places first, the intervening spaces to be furnished with the smaller branches and bearing wood. The main branches of Peach and Nectarine trees are destitute of buds of any sort, and to furnish the walls regularly with bearing wood it is desirable to train wood of last season close to or over the bare stems. Walls well furnished with healthy fruitful wood, skillfully trained, are a source of continual enjoyment; badly trained trees, with the branches running into each other, are eyesores and a disgrace to any garden, although otherwise it may be well kept.

Fruiters started early in January are throwing up fruit very freely. With a high temperature and a moderately moist atmosphere they may be expected to ripen-off in June and July. Smooth-leaved Cayennes and Charlotte Rothschild do not throw so freely as Queens, but they also are in some cases showing fruit. It is a good plan to water with weak manure water after the fruit shows. It has been recommended by some to withhold water until the fruit shows, but when water is withheld from plants that are in a moist atmosphere and high temperature they are apt to suffer injury. If it is desirable to throw all the plants into fruit at one time, and some of them are erratic, give just sufficient water to moisten the ball, and do not water again except so far as to prevent the young fibres from receiving injury. This is the evil to be avoided in the case of keeping any plants too dry for a purpose, for if the points of the small hair-like roots are killed, the chances of success are weakened to an enormous extent. We have not yet potted the young plants raised from rootless suckers in August last year. We find it necessary to grow them in a low pit where the temperature cannot be kept up over 55° in cold weather, whereas to grow the plants well 60° to 65° would be better. We hope to have an opportunity to pot them in a week or two; they are now growing very well in 6 and 7-inch pots. If possible they will be repotted in 11 and 12-inch pots, using good turfy loam with a fifth part of decayed manure and a 9-inch potful of crushed bones to each barrowload of loam. We were very unsuccessful with the Pines when driven to use our own light sandy loam, but when a good yellow slightly unctuous loam was obtained an improvement was evident in larger and better fruit. In our own soil the growth was all that could be desired, in fact dead better than in the mere clayey loam, but fruit did not show so quickly, and when it did the pits never swelled well; it seemed that all the potting material became exhausted in the formation of large leaves. See page 87 for instructions as to air-giving, &c.

PEACH HOUSE.

This is excellent weather for fruit setting. Indeed it is a

question whether January has not been a good month for forcing Peaches, notwithstanding the enormous rainfall. The weather has been mild, and air could be admitted freely. Windy days were prevalent, and it has been stated that in countries where the Peach does well as standards in the open air cold winds are frequent when the trees are in flower, yet the blossoms set well. A distinction, however, must be made between cold winds and frosty winds; air-giving must be conducted with caution when their icy breath freezes the ground under our feet. In the earliest house the fruit must be all well set, and it ought to be freely thinned-out before it injures the trees. The first thinning should be made when the fruit is well set, and the last at the commencement of stoning. Syringe freely on fine days, and as in the case of Pines, close early to utilize sun heat. The great importance of making sure that the inside borders are not too dry has been frequently urged; if the roots are in an over-dry medium failure is certain. Even this may occur when the gardener thinks that everything is all right. A rich dressing of loam and manure is placed over the surface, with the result that the surface waterings keep this constantly moist, while the soil beneath may be dust-dry: see that this is not so. Of course where the roots are outside and not protected in any way, except by a covering of leaves or some similar material, the soil will be wet enough. See that the Peach aphid does not gain a foothold on the leaves. Syringing will not destroy this pest. Fumigating with tobacco smoke is the best remedy, but it is sometimes necessary to smoke three times before the insects succumb.

Strawberries in Pots.—The first flowers of Black Prince were open some time ago, but owing to the temperature of the house having been too high and insufficient ventilation they have not set well. The first sign of anything being wrong was the petals not dropping. When the petals hang on and increase in size it is likely to follow that the centre will be a blank. Later blooms have set well, for as soon as the state of matters was observed the temperature was lowered a few degrees, and more air was admitted. We now water freely with manure water until about the time of the fruit colouring, when the water is withheld. Succession plants may be introduced into a higher temperature at once, as they are now on the move in cool houses. Plants intended to fruit just before those out of doors, are stored on the shelves in the orchard house; they require water about twice a-week.

FLOWER GARDEN.

Florists will now have plenty to do if they have full collections of what are usually designated florists' flowers. Auriculas, if not already done, must be surface-dressed by removing an inch or so of the old surface soil and replacing it with some rich material. We began this work on our own collection the last week in January and finished last week. Some few of the plants were wintered by way of experiment. The Auricula wakes up from its winter sleep about the end of January or first week in February, and root as well as top grows with unwonted vigour, and it may be that if potting is performed at this time a good result would follow. The plants will at least make vigorous growth. All rootless offsets put in about September or early in October, if they remain through the winter without producing any roots, they will strike out roots at this time and start into free growth. A quantity of offsets were also put in at the time of surface-dressing the pots; they root well in open frames at this time, and ought to be put in round the sides of small pots in loam, sand, and leaf soil in about equal proportions. There is every promise of an early bloom this year, as many fine trusses are already far advanced. The plants ought not to suffer for want of water after this time. And ventilation is rather a ticklish question. The plants must have plenty of air, but the trusses are weak on the stem and likely to lean over. Although we tie them to neat sticks for the flower shows, these are not wanted on the home stage, except in the case of a very few weak-stemmed sorts. The Manchester growers disdain sticks, even at an exhibition, and rather than show with them they will unstick the plants in the morning and place sticks to them again at night.

We ran the hoe through the ground amongst Tulips. These are coming up strongly. We have no blanks, although there has been so much wet that a fine bed of the old Giant Drompton Stock has been quite destroyed. On the first favourable opportunity a bed of Pansies will be planted out; these have been wintered in pots and the pots placed in a cold frame. Carnations and Picotees are making a start into growth, and if the present mild weather continues we shall begin potting-off the plants.

We are putting in cuttings of any bedding plants of which the supply is not sufficient. Verbenas, Ageratum, and other plants of a similar free-growing habit are better as grown from spring-struck cuttings. All the zonal Pelargoniums have been potted-off or the plants have been planted in boxes. Stocks and Asters, if they are intended for early flowering, should now be sown in hotbeds, and all tender or half-hardy annuals may be treated in the same way. Roses are starting into growth, but we have not yet ventured to prune them.—J. DOUGLAS.

TRADE CATALOGUES RECEIVED.

W. Heuder & Son, Plymouth.—*Illustrated Catalogue of Vegetable, Flower, and Agricultural Seeds.*

Laird & Sinclair, Dundee.—*Catalogue of Seeds, Roots, and Garden Requisites.*

André Leroy & Angers (Maine et Loire), France.—*Price Current of Vegetable, Flower, and Agricultural Seeds.*

Harrison & Sons, Leicester.—*Catalogue of Choice Seeds for the Garden and Farm.*

B. S. Williams, Victoria and Paradise Nursery, Holloway, London.—*Catalogue of New Plants.*

TO CORRESPONDENTS.

* * * All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

BOOKS (S. W.).—Cuthill's "Market Gardening Round London." We know of no work devoted to seed-growing.

RED-SKINNED FLOREBALL POTATO (H. Hill).—Although it does not succeed in your soil and situation it may on others. We are pleased to read that you have established an Amateur Gardeners' Society at Astwood Park.

LAWN MOSS (A Constant Subscriber).—From now to the end of March, in mild weather, lay the lawn well scratched with a new iron rake so as to bring up and remove the moss. The more you remove the better; clear it off. In March give a good dressing of decayed manure or rich compost, spreading it evenly, and not more than half an inch thick. In April rake again well with the iron rake, removing any rough and unsightly portions of the manure and any stones, and with an early prospect of rain sow over it evenly 5 lbs. *Pestuca duriacina*, 12 lbs. *Cynosurus cristatus*, 5 lbs. *Pestuca tenuifolia*, 8 lbs. *Poa nemoralis* sempervirens, 8 lbs. *Trifolium repens*, and 4 lbs. *Trifolium minus*, in mixture for 1 acre. If you are troubled with birds, rake lightly with a wooden rake after sowing; if not, simply roll well; rolling should also follow the sowing. Let the grass grow until the middle or end of May, then mow with a scythe, and afterwards keep under with the mowing machine. If the lawn is wet the moss would be subdued by draining.

BRIARS (Tyro).—I do not, of course, know who your correspondent's brother is, but I would recommend him to go into some large nursery, and if he does not find a very large proportion of the Briars there "green" I will own that I am entirely in the right. The subject connects with Rose-growing. The varieties of Briar are legion; but the younger they are, provided they have sufficient stamina and stoutness, the better. Some Briars brown in colour are very good, but my experience proves that the green are the best. A man once brought me a Briar 6 feet high as green in colour as I could get. Would "Tyro's" brother say that it was only one year old?—WILL SAVAGE.

BARBAROSSA AND GROS GUILLAUME GRAPE (Devout Reader).—The Gros Guillaume Grape was introduced some years ago under the erroneous name of Barbarossa, and this has adhered to it more or less ever since, but it is being gradually dropped. The true Barbarossa is not in this country, though one very similar to it is occasionally met with, called Gromier du Cantal.

CABRET-BEEDING PLANT (J. Carrick).—The only low-growing, dark-foliated, hardy plant that occurs to us as being suitable for your requirements is *Oxalis corniculata* rubra. Seed may be sown now, and the seedlings be raised in heat and subsequently hardened-off the same as *Lobelia* and other tender bedding plants. The *Oxalis* grows about 3 inches high, and the foliage is of a dark coppery brown colour. The plants grow freely in almost any soil, and are rarely or quite hardy.

SPHAERUM FOR ORCHIDS (E. J. B.).—It should be used in a fresh state though many prefer it dried, as it is then more readily chopped-up, and the dust or smaller particles can be rejected the more readily.

SEEDS FROM INDIA (J. L.).—*Poinciana regia* is a stove evergreen shrub or tree, thriving well in turfy loam, with a third of leaf soil or thoroughly sieved manure, and a sixth of sand. A little peat may be added if the loam be deficient in fibre. The seeds should be sown in a brick bottom heat (90°), in early March, previously stepping them in water at a temperature of 110° for twenty four hours. *Lagerstromia speciosa* is an evergreen stove shrub-like tree, succeeding in peat and loam in equal parts with a half part of leaf soil and a free admixture of sand. The seeds should be sown in a brick bottom heat early next month. *Combratum grandiflorum* is a stove shrub, succeeding in a compost of peat and loam. It is necessary that the seed be sown in brick heat to spring, drying the plants in moist heat during the summer, keeping them under glass in winter. The seedlings should be potted-off singly when a large enough.

PACHINO CIMONANTHUS FRAGRANS (H. G. M.).—Cut it back after flowering, and restrict the summer pruning to the removal of irregular growths.

OXALIS VESICULOR NOT FLOWERING (Idem).—We can only attribute their not flowering to the crowded state of the bulbs. They should have at least twice the pot room, and be given a good season of rest, not withholding water until the growth ceases, repeating when growth commences. A compost of turfy loam and a little peat and leaf soil will grow them perfectly. They should have a light airy position in a greenhouse, watering freely during growth, but not making the soil sodden.

TODEA SERRATA (Todea).—The old fronds usually go off about this time, or when the young fronds are being made. The old fronds will require to be cut away after the plant has furnished itself with new growth. Continue it in the cool house, in which it will do better than in an intermediate house.

PLANTS FOR INTERMEDIATE HOUSE (An Old Subscriber).—The Vines will give you all the shade required during summer; and in winter, from October to March inclusive, no shading whatever is required. Your house will be suitable for such flowering stove plants as *Allamanda nerifolia*, *Apelandra aurantiaca*, *Rozelia*, *Centropogon Luceana*, *Conoclinium lantianum*, *Dalechampia Boziana*, *Passiflora*, *Epiphylum truncatum* var., *Erantemma pulchellum*, *Euphorbia splendens*, *Franciscia calycosa major*, *Gardenia florida*, *Inantophyllum miniatum*, *Lasiandra maritima*, *Lasiandra floribunda*, *Libonia floribunda*, *Mocochetum esuferum*, *Plumbago coccinea superba*, *Scutellaria Mocciniana*, *Rogiera grattissima*, and *Vinca alba oculata*. Variegated or foliage—*Cyperus alternifolius variegatus*, *Drosera striata*, *D. bicolor*, *Franciscia confertiflora*, *Franciscia variegata*, *Piptotis (Gymnostachyum) Pearcei*, *Fandanus elegantissimus*, *Panicum variegatum*, *Panicum thalictroides*, *Pavetta borbonica*, *Sauzebia nobilis variegata*, *Maranta zehra*, and *Tillandsia aculis zehra*.

PLANTS FOR LARGE CONSERVATORY (Leodiensis).—1. *Foliage plants*.—*Beaucarnea recarvata*, *Chamaecyparis Fortunei*, *Dasylium gracile*, *Cordyline indivisa*, *Livistonia australis*, *Dracaena elegantissima*, *Dicksonia antarctica*, and *D. squarrosa*, *Florimium tenax variegatum*, *Yucca aloifolia variegata*, and *Y. quadricolor*. 2. Flowering plants.—*Rhododendron Countess of Haddington*, *R. Dalhousiana*, *R. Princess Royal*, *Lucania grattissima*, *Abutilon vellicerium* *marginatum*, *Habrothamnus elegans*, *Cianthus puniceus*, *Camelia* *alba* var.—*White*, *Alba*, *Pleura*, *Dominica*, *Fumibrista*, *imbriata*, *Mathotiana*, and *Elzeugus*.

KEEPING LATE GRAPES (S. G.).—After the fruit is ripe the night temperature should be about 45°. It does not injure the Vines much to allow the Grapes to remain, provided they are cut before the sap rises.

CLEO ROOT (E. M. P.).—If the gas company will not let you have half a bushel of gas lime, we do not know where you can purchase it.

OCUMBERS UNHEALTHY (J. G. Bristol).—Remove the unhealthy growths, top-dress to induce surface roots, water copiously with tepid water, and raise the temperature of the house, increasing also the atmospheric moisture, and we think your plants will prosper.

CIMINO ROSES (G. I. H.).—All inquiries must be sent to the Editors. Many correspondents would be annoyed by private letters.

VINE BLEEDING (T. E. D.).—Char the bleeding surface again, and deeply; then rub-in a paste made of gesso and lime.

CLEO-ROOT (J. C. M.).—It is caused by a weevil, which deposits its eggs in the bark of the roots. If the roots are dipped into a paste of soot and water at planting time, and then sprinkled over the surface of the soil, you will find the weevil destroyed.

PROTECTING FRUIT TREES (J. Rogers).—The "best," that is the most efficient coverings, are light domes or canvas, but these must not remain over the trees, and a system of rollers becomes necessary for raising and lowering the protection according to the weather. The "cheapest," for remaining over the trees, admitting light and air, and affording protection from slight frosts, is stout rooily twine netting.

FUNGUS ON CAMELLIAS (W. B.).—There are eight signs of black fungus on the leaves set, but the incrustation is principally caused by dust and sooty particles from the atmosphere. Spruce the leaves with a strong warm solution of soft soap, and then syringe regularly once or twice a-day throughout the season of growth. The leaves do not appear to be unhealthy, but they are not so healthy as they would be, unless you take prompt and efficient measures to clean them and keep them clean.

NAMES OF FRUITS (Gregory).—Cockle Pippin.

POULTRY, BEE, AND PIGEON CHRONICLE.

LOWESTOFF POULTRY, &c., SHOW.

THE ninth Exhibition of poultry, Pigeons, and cage birds was held in the Public Hall, Lowestoff, on the 7th and 8th inst. The birds, although not numerous, were very good, more especially the Pigeon classes, scarcely a pen being without a card. The Hon. Sec. (Mr. L. Wren), as usual, was very active and obliging, and the birds were well attended to.

Dorkings headed the catalogue. A fair class. First a good pen; second almost as good. *Cochins*.—First and second Lady Gwydyr, both pens exceedingly good; third very yellow. *Brahmas* (Dark).—Lady Gwydyr again taking first and second honours, which they deserved. *Brahmas* (Light).—P. Haines, the well-known Light Brahma breeder, taking first and second. The first pen grand birds, but slightly out of condition. *Game* a poor class, very little to choose between the first, second, or third, all the winners being *Game*. *Reds*, but lacked the gipsy pen so much desired. *Spanish*.—First grand birds, the hen having an immense comb and face; second very fair birds. *Hamburghs* (Gold or Silver-pencilled).—The third (W. K. Ticker) we preferred to either the first or second, third being placed in a very dark place. *Hamburghs* (Gold-spangled).—As a class poor, but well placed. *Hamburghs* (Silver-spangled).—Combs of all the winners much too large. *Hamburghs* (Black).—A rather better class. Pen 72 too late; would have stood a good chance of winning. *Bantams* (Game) a poor class. *Bantams* (Black) good. *Bantams* (any other variety) a fair class; the winners very good *Sprights*. *Bantams* (Selling class).—Third (Black Reds) would have won in the open class. *Ducks* should have been divided into two classes at least.

Pigeons.—Carriers three classes, exceedingly good. They must have given Mr. Hutton, who judged them, much trouble in a reward of the prizes. *Barbs* good classes. *Dragons* a grand class for a local show. Pen 247 too late; would have run the winners very close. *Tumblers superior*. 296 pen first (Yardley), a good bird, but unwell; have been, to all appearances, overshadowed. *Pouters* a grand class. First and second will in all

Any other Variety.—First one of the best Blue Priests we have ever seen; second a Black Russian Trumpeter; third a Blue Fairy Swallow. Reading and its neighbourhood boast many local fauciers, and the classes for them were well filled.

Captain Norman Hill judged the Pouter classes; Mr. W. B. Tegetmeier the Dragoons, Antwerps, and Variety classes; Mr. F. Esquilant the rest.

We must not pass over the *Cage Bird Show*, which was lovely. Every variety of Canary was well represented, and we were glad to see well-filled classes of British birds. Twenty-four Bullfinches, sixteen Goldfinches, twelve Linnets, besides Blackbirds, Thrushes, Blackcaps, and a most tuneful Dove which cooed incessantly. The classes for foreign birds were some of the best we have ever seen. Mrs. Monk showed a most varied collection of Parrots, her aviaries almost rival her kennels. Cardinals and Virginian Nightingales seen this year in peculiarly good condition. We thought Mrs. Monk's Mule resplendent, one of the most glorious birds we have ever seen. It rightly divided first honours with Mr. Williams's "Green-Leeks," a charming variety of Parquets. The Corn Exchange was well hested, and we thought the Show generally a decided success. Mr. Blakston judged the cage birds.

SPRING DUTIES.

DURING the winter months many bees die by reason of age, and lie on the boards of the hives till they are removed by the surviving bees in fine weather, or till they are swept off by the hand of the bee-master. In cold weather and long storms, when bees cannot leave their hives, their droppings accumulate on the boards too. In early spring it is desirable to scrape all offensive matter off the boards, so that the bees may commence operations for the season in clean sweet houses. On the first day of this month all our hives were turned up and examined, and their boards cleaned. Owing to the bees being able to leave their hives during the mild winter, comparatively few dead bees were found, and a little dirt.

Mild winters are evidently more conducive or less hurtful to the health of the inhabitants of hives than cold frosty weather. Of course, in open favourable winters bees eat a little more food than they do in cold ones, but this fact is so well known that practical bee-keepers consider and provide for a little difference of consumption. It is always well to be on the safe side, and see that none of our industrious favourites perish for lack of food.

As the weather is mild, and indicating an early spring, bee-keepers in the south may now begin to stimulate their bees by slow and gentle feeding. One halfpennyworth of sugar melted in boiling water given to a hive three or four times a week will speedily cause the bees to commence breeding. This artificial feeding should be continued till outdoor work commences. This gentle continuous spring-feeding is helpful, as it promotes either early swarming or early springing. In my own apiary I shall not begin feeding for some time for this reason, that many of my stocks were created in October and November of last year by syrup-feeding. They have no bees bred in them. I do not wish them to begin breeding till the bees are able to find pollen on the flowers of this spring. The bees which I fed into stocks were obtained very late last autumn, about six weeks later than the usual time. Stocks created in September by artificial feeding are generally very strong, and equal to all the wants of nursing and working.

As soon as breeding commences hives should be kept as warm as possible. In my case it is easier to preach than to practise on this point, for I have so many to cover that I can never get materials enough to keep them all warm. Old sacks and matting, or carpets, blankets, and old garments are gathered up for this purpose, and used as the under flannels of our bee hives. All hives should be well covered and kept warm in the months of February, March, and April.—A. PERTICREW.

DEATH OF STOCK OF BEES,

"A BEE-KEEPER" says, "One of my stocks was very strong last summer, but would not swarm. The bees hung out in large numbers night and day, and stopped up the door of the hive, preventing air from getting in, and thereby suffocating as many as would have made a good swarm. After the dead bees were removed, the living bees found sufficient room inside. In the autumn I fed them with as much sugar as they would take. A few days ago I found that all the bees had died; the hive and board together weighing 25 lbs.—weight of hive and board without the combs 12 lbs., honey and combs 14 lbs. Can any of your correspondents inform me as to the cause of the bees dying with so much honey in the hive?"

It is impossible to say with certainty what caused the loss of this stock. The suffocation of the bees in the summer resulted from instantation on the part of the bee-master, as bees never voluntarily suffocate their associates or endanger the lives of their fellow workers by preventing air from entering the hives. The clusters which are formed over the doors of hives are sometimes drowned or chilled by rain and fall down, and thus close

the doors and choke the bees inside. Suffocation is produced by dead and dying; not by living active bees. Clusters of bees hanging about the doors of hives should be securely protected from rain. Ultimately your hive perished from want of bees; in other words, from not breeding young bees enough in the autumn. But nobody, in the absence of sight or an examination, can say why bees enough were not bred in the autumn. The queen may have been suffocated, or the centre combs may have been filled with foul brood, or too well filled with honey and syrup.—A. P.

OUR LETTER BOX.

HAMBURGHS AT WOLVERHAMPTON.—Your reporter, in his criticisms on Wolverhampton Show, says, "The first prize pen of Gold-pencilled contained an old cock, which was rammed in the same position at Birmingham." He is in error, as my old cock was not shown at Birmingham, and is the one we won very many first prizes with in 1875, and was not in feather for the large shows. Please correct this in your next issue, and oblige—G. J. DECKWORTH.

FEATHER NOT DYED (R. L. G.).—We have submitted the feather to every test we know—alkali, ammonia, and acids of every sort. We can detect no traces of colouring, nor do we believe his feather has been tampered with. We cannot see what object they could have, as there is nothing in the colour contrary to a Pile. It is such an one as would be almost essential in a Worcestershire Pile.

HEN BREASTING HER EGGS (S. A. Z.).—Probably the egg-passage is inflamed. Give the hen a dessert-spoonful of castor oil, lettuce leaves, and no corn. Avoid cabbage leaves unless they are boiled.

DREBBING (R. W.).—We stated in our Journal on the 25th of January that we decline entering on the subject. We have too many letters on both sides to induce us to alter our determination.

PULLET DROPPING HER EGGS (A Constant Observer).—Give her a table-spoonful of castor oil, lead on barley meal wash, and give her lettuce leaves daily.

RATS IN POULTRY HOUSE (R. W.).—We have tried most things, but have found nothing so efficacious as having numbers of cats in the places where the chickens are kept. We have no difficulty in accomplishing it if we bring up the kittens among the poultry and feed them. The rats will not come where the cats are, and the cats will not eat the chickens unless driven to it by hunger. Our chickens are at present under cover. We shall soon put them out, then we move the cats into the field with them, supply them with small butches, and tie them by means of a long string. We lose no chickens by rats. We generally ferret the haunts of the rats about once in a month. We have some good dogs, and we kill many rats. They must not be allowed to "rest and be thankful." If they are continually disturbed they will at last shift their quarters. The best traps we know are Braileford's, and the most destructive engine is the gin. It can be covered with paper, lines, or sawdust, if put in a run; if exposed it must be baited. We know no bait better than red herrings.

FANBERS (W. C.).—We know of no book upon their management.

REMARKS.

- 7th.—Very fine all the forenoon; dull in afternoon, and rain in the evening.
- 8th.—Fine morning; a beautiful day, bright and warm.
- 9th.—Rather cold and less bright than the previous day, but still a fine day.
- 10th.—Fine morning; very slight shower at noon, but soon over; wind rather high at night.
- 11th.—Rain 6 to 8 A.M., fine at 9, and followed by a brilliant day; less and still more brilliant starlight night; afternoon bright at midnight.
- 12th.—Very rainy in forenoon; afternoon bright and fine.
- 13th.—Fine morning, rain at 10 A.M. and at times all day; very dark about 4 P.M.

Mild week, damp air and westerly wind.—G. J. SKIMSON.

COVENT GARDEN MARKET.—FEBRUARY 14.

All classes of goods are now getting into a small compass, and with business better, prices have somewhat improved. All kinds of early forced vegetables can now be had, and are commanding fair prices.

From observations taken near London during forty-three years, the average day temperature of the week is 47.3°; and its night temperature 33.2°.

THE AURICULA.

HIS pretty spring flower is now beginning to make rapid growth, and many of the earliest trusses are considerably advanced; they are beginning to repay the ardent cultivator for many months of attention.

The plants now require more care—shelter from biting winds and sharp frosts at night—than they do at any other season of the year. It will be well to double-mat the frames if the thermometer is likely to register 8° or 10° of frost. All the plants ought to be surface-dressed before the second week in February; this of course depends to a certain extent on the weather. I have known a severe frost set in about Christmas and continue until February. The soil in the pots would in that case be frozen hard and could not be touched until mild weather. After the surface-dressing is applied, which ought to be of moderately rich material—about two-thirds loam to one-third decayed manure and a little sand and leaf soil—the plants ought not to suffer for want of water at the roots, and it ought only to be applied to the roots; the fine mealy-foliaged sorts are utterly spoiled when the leaves are drenched with raindrops or water from the pots. At present the foliage of Topsy, Trail's Beauty, Taylor's Glory, Smith's Ann Smith, and many others, as it is increasing in growth is extremely beautiful and ought to be as carefully preserved as the pasts in the centre of the flowers or the white-powdered edge. We often hear of the fine flowers that used to be grown half a century ago, but when one reads of the treatment (and I do not now allude to the over-rich composts, but to the way the plants were exposed to the weather in early spring) it almost makes one shudder. After the blooming period is over a shower is not of so much matter; but one of the principal growers, Mr. Hogg of Paddington, who took lessons from Emmerton, Kenny, and other growers, says in his treatise in reference to the treatment in March—"Let the lights be off all day if the weather is in any degree favourable, and let the plants receive all the soft and gentle rains that fall until the pips open. Protect them, however, from cold elets and snow and cold cutting winds." In February he says, "If any of the plants require shifting into larger pots now is the time to do it," and, again, they are to have plenty of rain—"at least rain sufficient to reach the roots at the bottom of the pots, and this may be repeated when necessary through the month." What grower north or south would treat their plants in that way?

Auricula shows were very frequent at that time, and fanciers would go to much trouble and expense to win the blue ribbon, a silver cup. Hogg gives an amusing account of the trials of a gentleman holding some office in the India House whom Emmerton had imbedded with the Auricula fancy, and who under his directions was confident of winning the silver cup. He purchased about one hundred plants of the best sorts; but Emmerton contended that without bullocks' blood and goose dung

they would stand no chance. He persuaded his pupil to commission some country waggoner out of Sussex to bring him at midsummer two geese and a gander, which, according to Emmerton's calculation, would produce dung enough by Christmas to last him two years, when they would be fat and fit to kill, and well adapted for good fare wherewith to treat his friends at that joyous season. This project was soon put in execution. The geese were brought to town and cooped up in a corner of his small garden, which might be 10 yards long by 5 wide. Everything was going smoothly; the plants grew and the dung accumulated; only the man's wife complained of the filthy smell arising from the heated and fermenting dung, but Emmerton promised soon to remedy that evil by covering it with loam. Notwithstanding, as the dung increased and was stirred up with the blood, the stench increased too, and became so intolerable that the women living at the two adjoining houses joined their complaints with hers, and abused him whenever he made his appearance. Emmerton finding the storm gathering in earnest judged it prudent to decamp, telling them that the London ladies were too fine-nosed by half; but he never dared to repeat his visits afterwards. This was only a prelude to the vexation which the gentleman had to experience himself. "One day when absent at his office the door of the coop was left open, and the geese finding themselves at liberty waddled about the garden unnoticed; and having been deprived of grass and green food so long, fell upon the Auriculas in the frame, pecked, bit, and pulled them out of the pots, trod over and spoiled them so completely" that they were of little use afterwards. Emmerton seems to have been unfortunate, not only in business, but in other respects; he libelled the parson of his parish, a magistrate withal, by hanging him in effigy on a tree amongst his Auriculas, for which offence he was indicted, and suffered a year's imprisonment in the King's Bench.

The Auricula-growers now make no secret of their composts. I have already told all I know about them in these pages; and about two years ago three of the best articles I have ever read were published in this Journal from the pen of the Rev. F. D. Horner of Kirkby Malzeard, Ripon. The lists of varieties need not be altered yet, and the cultural directions are complete.

We are all looking forward to the great show to be held at the Crystal Palace April 24th. It promises to be such a show for magnitude as has not been held in England before (of the Auricula, of course). There will be very little restriction in the schedule; it has been framed to admit of as many competitors as possible. And in this respect it rather differs from that of the National Society at Manchester. In that schedule the "pans" of six must have all the classes represented—that is, green, grey, white, and self edged; and in a class for twelve pots they would suggest that there should be at least two plants from each class. When a grower has a large collection to select from he can easily do this, but a small grower might not possess the stipulated number of the different classes, and yet might be able to arrange an effective

group; and this could be done if one of the classes was to be quite left out of it. Of course such a one could not stand before an exhibitor who had all the classes represented and of equal quality. Variety in classes must with a competent judge stand for something. A case in point occurred at one of the provincial shows of the Royal Horticultural Society. A set of prizes were offered for "the best six Pine Apples." One exhibitor had staged a collection in, I think, three varieties, when a friend of mine said, "I intend to put up six, but they are all Queens. How will I stand against that collection?" I said it was very likely that the judges would give a little in favour of variety—perhaps a point or so. "Well, then," he says, "I will not stage mine. I think they ought to stand upon their merits alone." He did peek them up, and was about sending them back to the station. However, I urged him to bring them out of the box, and my friend was easily first with his Queens; their quality quite overbalanced the variety of his opponent. Had the fruit been about equal in quality the tables might have been turned.

Placing sticks to the trusses of Auriculas is a sore trial to northern tastes. Down south we do it without the least compunction; we fancy it is an improvement. The northerners say the Auricula needs no support. There are a few other immaterial points, but it is most likely that we shall learn from each other, and who knows but the rules and regulations will be the same next year?

Next to the show or stage Auriculas come the Alpines, and here again north and south are at issue. It seems there are shaded and self Alpines. In the north only the shaded flowers are admitted in competition. Were some of the fine varieties raised by Mr. C. Turner of Slough, admired by all the frequenters of our exhibitions, and certificated by the Floral Committee of the Royal Horticultural Society, exhibited for competition at Manchester they would be disqualified—that is, if they had the edge one decided colour—unshaded. A true self—that is, a flower with white paste, must be unshaded; it must be self-edged. The true Alpine has a yellow centre, and it must be unshaded. I would just like to put this question to our northern friends, What right have you to make this distinction? One of our best florists writing the other day in a contemporary says, "Seedling-raising is an admirable school for teaching humility and opening the mind and heart to the limitless power of the Infinite." Why then should we limit that power? I cannot yet see why we should let one class of flowers quite override another and equally beautiful one. Perhaps some of our friends will kindly explain it to us.

Then we have the Polyanthus. Mr. Dean of Ealing has taken in hand the border flowers and improved them by selection. They are well adapted for decorative purposes, and they have been admitted at our southern exhibitions; why should they be excluded because they do not conform to certain rules laid down by florists half a century ago? The question for the judges would be first, Are they Polyanthuses? The next the quality of the flowers and their general effectiveness. If the old-fashioned flowers, such as Pearson's Alexander, Buck's George IV., Nicholson's Bang Europe, or Ekersley's Jolly Dragoon are superior to the improved border flowers let the judges decide.

I do hope that collections of the best Alpine Auriculas and Polyanthus will be sent from the north, and that we shall be able to have a friendly discussion about them. In making the above remarks I trust it will be understood that I write in no captious spirit, nor have I been prompted by any member of the southern committee. I am entirely responsible.—J. DETOLAS.

MUSHROOM GROWING.

This subject, although often written about, is by no means "threadbare" so far as regards every reader being able to put the printed instructions into successful practice. I have not always grown Mushrooms. I can remember the time when I knew nothing whatever about the subject further than what I read in the Journal and elsewhere, and then I often thought how difficult it must be to grow Mushrooms, and hoped I should never have occasion to do so, as, although moderately informed, I should be sure "to make a mess of it." Now I find growing Mushrooms to be one of the most simple affairs I am called on to perform, and I cannot see why it should not be the same to others.

All our beds this winter have done extraordinarily well so far. The Mushrooms have averaged in size from the tender

little "button" to the full form of a common tea-saucer. These latter when quickly grown are favourites with the cook, and so are the buttons, which is the name given to the Mushrooms when they are about the size of a coat button; but I do not approve of cutting them so small, because if they are only left for two days longer they will be three times as large and quite as good to eat; but although I recommend their being allowed to develop, I have cut a good many lately in a small state simply for the reason that they came up so thick in the bed that they had to be thinned-out to give the remainder room to spread. Some may say the spawn must have been excellent to produce such results; but I do not think it was anything extra, neither was the treatment to which the beds were subjected, everything having been done in a simple manner, as will be seen from the following brief description of my practice.

A barrowload of fresh horse droppings is brought from the stable every day. We make a bed out of about eighteen barrowloads; consequently it takes about three weeks to get sufficient together to form a bed. The whole of the manure is placed in an open shed. As each barrowload is added it is mixed with that previously laid down. It is thrown down loosely and spread out thinly, and during all the time it is drying it is never allowed to heat excessively or ferment. When the desired quantity is collected together it is cleared away to make room for a fresh lot. Before taking it into the Mushroom house it is turned over twice, and previous to doing this two or three barrowloads of open soil are thrown over the heap and the whole mixed up together.

In making the bed a beginning is made by placing a layer 2 or 3 inches thick all over the bottom, beating it firmly, then adding layer after layer until the whole of the material has been used. For a day or two after this has been finished nothing is done to it, and by that time the heat is becoming strong. The bed is spawned at this time by breaking the bricks into bits about the size of a walnut and putting these all over the surface, but 2 inches below it, and about the same distance apart. A cabbage dibble is used for making the holes, and they are left open for a night and are then closed over the spawn. The surface is beaten firmly and smoothly, and then open soil to the depth of 2 inches is spread all over it; this is also beaten firmly, and afterwards watered and smoothed with the back of a spade. This completes the whole operation. We begin cutting the Mushrooms from four to five weeks after spawning.

I think our practice differs in several points from that I have seen recommended. It is generally advised to let the heat rise in the bed and again decline before putting in the spawn. I question if this is always the correct thing to do. I have never tried and therefore cannot say what amount of heat will destroy the spawn, but I am inclined to infer from what I have observed that when the heat is allowed to decline it often does so to the extent that it has no power to move the spawn, consequently it remains dormant, and the bed is a failure. I find the best way to keep up a constant supply of Mushrooms is to make the beds small and often; ours are generally about 8 feet long and 4 feet wide. The house is always kept dark, and the temperature from 50° to 55°; a higher temperature has no advantage. We never syringe, but only damp the floor three times a day. Some beds are never watered from the first, but any that may become dry on the surface are given a slight sprinkling. In gathering we twist the isolated Mushrooms out by the roots, but those growing in clusters are cut, as drawing them often injures the others.—A KITCHEN GARDENER.

AURICULAS ATTACKED BY WOOLLY APHIS.

In answer to your correspondent John T. D. Llewellyn, page 96, respecting the use of Gishurst compound to his Auriculas attacked by woolly aphis, I beg to inform him that he may use it with perfect safety, although Mr. Horner, in his very great dread of using anything to our pets the composition of which he is not acquainted with, advises him not to do so. I had the misfortune to have my plants infested with the enemy last autumn, and as I report early (beginning of June) my plants had become well established when I first detected the aphis, and I was therefore very loth to disturb the plants; but knowing the danger to which I was exposed I resolutely made up my mind that however serious it might be to disturb them at that season, it could not be so bad as to allow the spread of the blight, and I therefore at once turned the affected plants out of the soil and washed them, root, stem, and leaf, in a

solution of Gishurst compound of the usual strength, and with, I am happy to say, the best result, for none of those so treated show any sign of the blight, nor are they now any worse for the remedy.

I am afraid this pest is likely to be a source of annoyance to Auricula growers, as I hear of it in more than one collection, and I know of one grower who, having just detected it, is treating his plants with Gishurst. I have also heard of it among Camellias and Vines. Have any other of your readers?—W.F.S., York.

ROYAL HORTICULTURAL SOCIETY.

MANY letters have been written and suggestions made for the better government of this Society. Some of the letters have been temperate, others intemperate. Some writers have arrived at "lame and impotent conclusions," and others have advocated a destructive policy. In fact it is only by a stretch of charity that we can believe that all who have endeavoured to "assist" it are really desirous of seeing the "old Society" prosper. Some of the letters, if one is to be curious enough to read between the lines, almost reveal a fear lest after all the patient should recover; but these are only a few and are not worthy of discussion, the majority having evidently been prompted by good intentions.

Probably no one has worked harder and with a better motive than Mr. G. F. Wilson, but, so far at least, the results have been "impotent" indeed and extremely disappointing. Who are there in the horticultural world who have read the many "encouraging" letters which have appeared in the press, who were not struck with amazement on reading the speech of Mr. H. J. Veitch as delivered at the meeting of the 13th inst.?

More than half of the horticultural world had begun, as it were, to acquiesce in the destructive policy on the faith of the tacit understanding that four thousand or five thousand "world-be guinea Fellows" were ready to hoist "the flag of freedom" and march in dignity to the goal of glory; but when these four thousand or five thousand dwindle down, as Mr. Veitch showed, to 273, and one-third of them are already Fellows of the Society, "what a miserable falling-off is here." I regret this exceedingly, for the best of all reasons—that I was a believer in the guinea scheme. I do not hesitate to say that I am deceived and almost humiliated. Mr. Veitch has brought me from the clouds to my humble level on mother earth, and I will not again listen to exclamations about "dignity" until I know that there is meaning and money attached to it.

I have again read Mr. Wilson's appeal and still think it good in principle; but after the tone of the meeting on Tuesday last, and the apparent utter inadequacy of the expected guinea response, I think the appeal would be greatly improved by taking out of it one sentence in parenthesis, yet very important—namely, "that the guinea fellowships do not come into force until the Society is free from Kensington." After having considered the matter in conjunction with the various statements and expressions of opinion which have come before the public, I think the removal of that condition would enable Mr. Wilson to do more substantial good to the Society which he desires to see prosperous than he can possibly do by its retention. Mr. Wilson has more than once expressed his confidence in the present Council, and has discontinued by anticipation any change; he knows also that it is impossible for them (however strong their desire might be to do so) to leave Kensington for a considerable time. It avours, therefore, somewhat of a dog-in-the-manger policy to be able to render aid and yet withhold it, at the same time that such aid cannot be effectively applied in another manner. That the Council also enjoys the confidence of the horticulturists is abundantly evident, or they (the Council) would not have the liberal and gratuitous support which has been so spontaneously rendered by all the leading metropolitan nurserymen. The Council are evidently a body of trusted officials ready and anxious to promote the interests of horticulture to the utmost of their power. Then why restrict any source of aid? Let the guineas come in as fast as they will from the country horticulturists; and as the Council have clearly expressed that "the manner in which the Kensington gardens are kept depends on the subscriptions of the Kensingtonians," there is no fear that the country guineas will be spent in mere town parade.

The Council, too, it appears, are willing to accept guinea Fellows, admitting each to the full privileges of the Society except voting, and some, in fact, I think have already joined.

I fully expected that some opposition would have been expressed at the meeting on the voting question as restricted by the Council, but so far as I can learn not one voice was heard against the Council's decision, although the meeting was largely composed of horticulturists, and included the editors of the gardening journals, and even also Mr. G. F. Wilson. Not one word in opposition to the official views was heard, but there was a really unanimous approval—the approval of silence. And after all what does the voting of guinea subscribers amount to? A long journey to vote on a matter which not one in ten would care to vote about, or at least would not incur the expense of the "privilege." I am sure I should not, and I am as willing to pay my guinea as a countryman without having a vote as in possessing that which I should not incur the trouble or expense of exercising.

So long as there is a distinction in Fellows' contributions so long must there be a distinction of privileges. It is so in all societies, and if the privileges are to be equal so also must be the contributions. If guinea Fellows, or whatever they are called, have a right to every privilege of the Society, everyone must command the right of being a guinea Fellow.

The Council are engaged in an onerous and thankless task; and what is their object? The establishing of the Society and the advancement of horticulture. What is their reward? The hoped-for aid of all who are as anxious as they are. Country guineas alone cannot save the Society. Country people have local societies to support, and only a small proportion will render aid to a national society also; but why should they be unable to do so on account of arbitrary restrictions? As an earnest of the Council to extend the influence of the Society, their last effort to incorporate local societies, giving them privileges and granting them medals, &c., affords ample proof. I ask that the unmerited distrust may cease, and that aid from all sources—local and general—be permitted to come in, for according to those who are best able to judge it is only by such united aid that the Royal Horticultural Society can flourish.

—A GUINEA MAN.

THE following letter has been sent to the *Pall Mall Gazette* by Sir Charles W. Strickland, Bart. :—

"Sir,—I am sorry to see that such a paper as the *Pall Mall Gazette* should advocate the breaking up of the Royal Horticultural Society, because it has unfortunately made the blunder of becoming a partner with the Commissioners in the making and management of the gardens at South Kensington. In the article in your number for last Thursday it seems to be assumed that the Society exists wholly, or at least chiefly, for the maintenance of this miserable tea garden. The writer of that article appears to be wholly unaware that the Society still does a good deal of valuable work in its proper sphere—that is, in the promotion of horticulture, and that if it could get rid of South Kensington, or could entirely separate the South Kensington account and its management from that of the Horticultural Society proper, it soon would do much more of its own work, and that it is for the sake of this work that I and many more of the older members of the Society continue to belong to it. I have invested four guineas a year for many years in the Society, and consider that I have a vested interest in it, and that it would be an act of injustice and robbery to break up the Society. And let no one delude themselves with the idea that they could set up a new Horticultural Society in the place of the old one. If I were to see all that I have spent upon the Horticultural Society thrown away, do you suppose that I should be such a fool as to begin over again and invest in a new Society? and I have no doubt that a large part of the members of the Society would feel and act as I should do."

CELERY CULTURE.

VERY soon preparations must be made for a supply of Celery for next autumn and winter. Celery is seldom wanted before October or November, and the beginning of March is a very good time for sowing the seed. If wanted earlier than the period named, of course the seed must be sown earlier; but it should be remembered that the plant is really a biennial, and would under natural conditions flower the second year, but under a course of artificial treatment it is started into growth much earlier than would be the case in nature, and when this happens it has a tendency, like many other biennials, to flower the same season.

The seed should be sown thinly in pans or boxes and placed in gentle heat, and as soon as the plants appear they should

be removed to a cold frame, giving plenty of air on all favourable occasions till the end of April, when the pans or boxes may be placed outside, so that the plants may be ready for pricking-out about the middle of May. The cones usually adopted is to prepare a bed and plant the small seedlings out about 4 or 5 inches apart, to be again transplanted into the trenches; but if the ground is vacant I recommend that the trenches be prepared and the seedlings be put out about a foot apart in them at once, taking great care in handling them; and if watered with a fine rose till the plants make a start they receive no check, as they must do when transplanted in the hot weather later on, for it is important that from the time they are first planted to keep them always in a free growing state. I have followed this course with good results, and the loss of plants in the rows was only two per cent.

The trenches should be made in an open position in the garden, digging them 9 inches deep, and placing in them about 4 inches of rich manure, and the nearer they are to the pump or tap the better, for without plenty of water throughout the season good Celery cannot be grown. When earthing-up is commenced, which should not be until the plants have attained a good size, the rows should be gone over to remove any side shoots, and a thorough soaking of water should be given the night before the earth is applied, being careful that the plants are quite dry before any soil is placed round them. The practice of pushing the soil against the plants in the form of a sharp ridge is bad, as it is liable to throw off all the water from the roots, and at that period of growth they still require a good supply, but at the final earthing it will be necessary to have the ridge-like form for throwing-off the rains during the winter.

Sandringham Dwarf White and Incomparable Dwarf White are two good white kinds, or perhaps they are synonymous. [Yes.] Manchester Red and Leicester Red are good red kinds, but if I were only to plant one sort it would be Leicester Red, for it is of good quality and flavour, and keeps sound in light soil till March.—A. H.

[We have seen the Celery grown by our correspondent both as exhibited at South Kensington and as growing in the garden under his charge, and we never observed better produce. We noticed that was the best which had been transferred direct from the seed-pans to the trenches without any intermediate transplanting.—Ems.]

EXHIBITION PANSIES.—No. 2.

WHEN advocating the claims of fancy Pansies I meant to do show varieties no injustice; I merely laboured for the recognition that is being tardily accorded the former. Some of the fancies which have been sent out are, I confess, sufficiently bad to dignify any true florist, and could only serve the purpose of deepening the pre-judice against the species. The bad varieties have been chiefly remarkable for size, and but for this characteristic would have left the seedling bed for the rubbish heap; but size without the other elements of a good flower is worth nothing, and the destination of such an one ought to be the spot indicated. One of this class, called H. W. Tugwell, Esq., was sent out in 1875 by a noted Fancy grower of Bath, and proved the most disappointing flower it has ever been my misfortune to purchase. When it bloomed I could not believe it was true to name, so different was it from the raiser's description, and I sent direct for another plant; but it was true, and at the same time very false, for instead of being of "large fine form, edged with rose, circlets of white, and blotch of lavender," it was the veriest mongrel ever sent out and unworthy of existence.

While, however, good fancies may be raised in comparative profusion, equally good show flowers are few and far between. Last year several were sent out, reaching the very highest standard of form, colour, and substance, and so good that it is difficult to believe they will ever have to give way for others.

Dean Ramey, sent out by Messrs. Dicksons & Co. of Edinburgh, is an exceedingly rich velvety crimson self, of exquisite form and ample substance, and one upon which an exhibitor may always depend, being constant, vigorous, and a free bloomer. Zama, raised by Messrs. Downie & Laird of Edinburgh, is a perfect yellow self, as round as a coin, and so smooth as to require no manipulation to make it lie down in the pan; it would, nevertheless, be better if it was a trifle bigger, but I hope next year to find it improved in this respect. Flag of Truce, by the same raiser, is of the purest white, and equal to Zama for form and quality. As far as I have seen

The Sultan (Dicksons) is the best new yellow ground, having a beautiful golden field, maroon belt, dense blotch, and is smooth, constant, and large. Close up is John Paton (Downie) with its bright purplish belt and very fine form, followed closely by William Martin (Dicksons), a primrose ground, rich chocolate belt, solid blotch, and a smoothness equal to Zama. A really good white ground, like a perfect self, is a *rara avis* in Pansy-raising, and when Messrs. Dicksons first saw Beatrice the thrill of pleasure must have been intense. Their own description of the flower is as follows:—"Clear white ground, very dark heavy purple belt, fine solid blotch, and neat eye; very large, of great substance, and always fit for exhibition;" and I can safely say there is not the least exaggeration. Unlike many white grounds it is a good grower, and unless shows occur especially fast, with care a good bloom may always be obtained. Messrs. Downie & Laird's Duchesse, too, is a grand flower, as is also Miss Todd. Of other new show varieties I may name Mrs. Henderson, P. W. Sime, William Forbes, and Demetrius (Cocker), but the list is necessarily short, as I only speak of those I have proved. The Queen, sent out by H. Hooper of Bath, I have kept purposely to the last, not because it is the best, but because it is the largest. As its raiser claims, it is "the largest white ground ever raised," but it has not done well with me; it has come so rough and uneven, and often ragged in the belting, but it has many of the properties of a good flower, and I shall try it this year under two or three varieties of condition.

Taken as a whole, the show flowers of 1876 are a good lot, and many of them are a vast improvement upon varieties previously in cultivation; still there seems to be too strong a desire to send out a long list of new sorts, and only under very exceptional circumstances can this be done without sacrificing quality to quantity. For myself I would rather send out one really good flower in five years than annually put upon the market a dozen or two of mediocre merit to the injury of my own reputation and the discouragement of those desirous of keeping pace with the times. I have suffered so much from the result of blind faith in raisers' descriptions that I have often half resolved to buy nothing which I have not seen in bloom; but as I cannot journey every year to Edinburgh, Aberdeen, and Bath, I am forced to select a few from each raiser, and give him the best order the following year whose descriptions are nearest the truth.

Next week I will give a brief list of older show flowers of merit and a few remarks upon cultivating and exhibiting.—M. H. MILLER, Leek.

NOVELTIES IN THE ROYAL GARDENS, KEW.

THIS RETICULATA is the finest of the herbaceous plants in flower at Kew. Its purple flowers relieved with orange form a dense mass which the slender leaves do not hide, but shooting above add greatly to the effect. *I. stytiosa* is also very fine, though the flowers are somewhat obscured by the stronger leaves. These beautiful plants, especially the former, cannot be too strongly recommended for the most liberal planting.

Many beautiful Orchids are flowering. The *Dendrobium* are represented by several fine species. A good specimen of *D. crassinode* has several stems thickly laden with rosy-tipped flowers. Of *D. Wardianum* there are light and dark varieties. *D. primulinum* is attractive and distinct in appearance, so also is *D. heterocarpum*. *D. Hillii*, of which there are several plants, is certainly one of the most effective. *D. speciosum*, to which the last may be referred as a variety, is also in bloom. *D. moniliforme*, *D. noble*, and the variety *pendulum* add much to the display, besides which there are several of less ornamental character. *Stenorrhynchis speciosa* is a rather rare terrestrial Orchid, easily cultivated and of much merit. It has crimson flowers, and conspicuous bracts which show the same colour almost from the first appearance of the scape. There is a variety with spotted leaves, and both are ornamental when out of flower. *Oncidium cheiroporum* is an extremely pretty species, of which a figure is given in the "Botanical Magazine" of this month. It has a neat small habit of growth, and the diminutive flowers are very numerous. They are bright yellow and sweetly scented. Other species are *O. aurum*, *O. reflexum*, and *O. flexuosum*. *Odontoglossum* are now in variety. These are *O. cordatum*, *O. gloriosum*, *O. nebulosum*, *O. triumphans*, *O. pulchellum*, *O. Rosellii*, *O. Rosellii superbum*, and *O. Lindleyanum*. In company on the same shelf are *Lycaste Skimneri*, *L. linguella*, and *Ada surattiana*. Among the *Cypripedium* are *C. venustum*, *C. biflorum*, *C. R. cal.*

C. pardinum, *C. Harrisianum*, and *C. javanicum*. Besides *Angreum sesquipedale* are *A. obnumm* and the variety *virous*, both of which are highly ornamental though less choice. In baskets near the *Dandrobiums* in the warm division are *Phalenopsis rosea*, *P. grandiflora*, *Saccolabium guttatum*, and *S. Harrisianum*, which often attracts attention from its agreeable perfume. *Epidendrum xanthinum* is a fine ornamental species, with dense heads of yellow flowers. The same may be said of *E. erectum*, with purple flowers. *E. fragrans*, though not showy, is of pleasing appearance and delightfully fragrant, on which account alone it is worth cultivating. *E. cochlearium* is of similar habit, and peculiar from its nearly black shell-shaped lip and narrow sepals and petals. *Laelia superbiens* has some beautiful heads of bloom, with which also is *L. anceps*. Of *Cattleya Trianae* there are fine light and dark varieties.

THE LILY.

In my communication of the 1st inst., when alluding to a show of flowers which had been made, as it was stated, by a bulb that had flowered the previous year, I said "it was the successor of the former bulb that produced the display, as a Lily bulb can only flower once—that is, during one season." Permit me now to explain.

In the first place, I ask, Is a Lily an annual or a perennial, or is it between the two, a biennial? The origin of a Lily bulb is a germ or seed bud. Nature causes this to vegetate or grow the first year, to bloom the second year, and then it dies—leaves, stem, scales, and roots all perish. Such is the short span of the existence of a Lily bulb. If a bulb that has flowered is taken up, say late in the next autumn, and cut in two vertically, it will be seen that it has within itself three distinct generations—that is, a portion of the parent bulb which has flowered this year, 1877; the whole of a new bulb which Nature destined to flower in 1878; and a germ or seed bud which was intended to grow up a full-sized bulb and flower in 1879. At this time, the autumn of 1877, the seed bud will be so minute as not to be perceptible without the aid of a magnifying glass, but if a similar bulb is taken up in January, 1878, and dissected the seed bud will then be perceptible to the naked eye, as it will be about the size of a snary seed, and will, if the scales are picked off carefully, be found in the axil between the inmost fleshy scale and the base of the new flower-stem. I send you a slice, marked No. 1, of a bulb I cut open last month; it is now considerably decayed by exposure, but still you will perceive the seed bud at the base between the scales and a portion of the new flower-stem. No. 2 is a portion of a bulb I took up only two days ago. It is a very fine fresh specimen, as I was careful in picking off the scales. At the base of the flower-stem which was destined to flower this year you will see the seed bud eight or ten times larger than No. 1, showing the comparative large increase in growth it has made in only one month. This seed bud was destined to become a full-grown bulb and flower in 1878.

The plan that I adopted in order to trace the progress of the seed bud as it grew up into a fully-formed bulb was this:—In October, 1873, I lifted some fifty thoroughly matured bulbs and replanted them in a piece of spare ground. In January I commenced by taking up two or three, cutting the bulbs vertically in two, and otherwise dissecting them for the purposes of my experiments. In this month I found the seed bud, as I have said, about the size of a snary seed. In this manner I continued to lift two or three bulbs every month up to the following October, in flower or not, as the case might be, and noted the progress of the seed bud until it had grown up similar in size to one I had cut and laid open for inspection in the previous autumn.

By this simple experiment it may be proved in the most satisfactory manner that the parent bulb of this year, after having flowered, and after having all the sap absorbed from its scales for the nourishment of the new bulb, decays and dies. In like manner its successor flowers the next year, decays and dies; and so on, one generation following the other year after year, and all emanation from germs or seed buds.

There are some professional Lily-growers who have very strange notions about the physiology of the bulb, who have passed round and round about it for many years, who have actually stumbled over it without apparently having perceptive powers sufficient to grasp its very simple details. Messrs. Teutschel, the extensive growers and importers of the Lily, in their observations say:—"What is the bulb but a receptacle

of stored up force during the winter months to preserve life and perpetuate spring growth?" Again:—"A yearly increment of growth occurs in healthy Lilies in the interior of the bulb, the outer and old scales are pushed further apart by the new growth, and the bulb increases in size more or less according to the nature and health of the bulb." Again:—"We have constantly observed when Lilies are taken up that there are two sets of scales, the outer irregular discoloured portion, which represents all that is left of last year's bulb, and an inner, regular, plump, white set of scales, representing the growth of the previous and the inflorescence of the coming season." Now, what possible information can passages like these convey to the mind of the inquiring amateur? They can only bewilder and discourage him. Another extract and I have done. Messrs. Teutschel say:—"A bulb will send up two or more stems. At the close of the season it will be found that each stem has acquired a separate bulb, and that two, three, or more bulbs have been formed out of the original parent."

With reference to this last extract, which very imperfectly accounts for the phenomenon, we know that almost every scale of a fresh ripe bulb could be made to germinate, but not while they are connected with a growing new bulb, as such a bulb draws all the nutriment out of the scales of the parent bulb until the parent decays and dies. There are, however, sometimes more than one seed bud which grows out of the new bulb altogether independent of the parent bulb, and this gives rise to the phenomenon of what is properly called twin-bulbs. As an illustration of the fact I send you the half of a specimen bulb which I took up last October and cut in two. It is shrivelled up by exposure to the atmosphere, but still you will see that there are two finely formed twin-bulbs, and behind, and entirely distinct from them, is the decayed stump of last year's flower-stem. These bulbs are equal in size, and show each the rudiments of a new flower-stem, and had the parent bulb been left in the ground or replanted these bulbs would doubtless have both flowered this year. Look at the remains of the parent bulb; if it had been allowed to remain in the ground these twin-bulbs would have been much larger than they are now, and the remains of the parent bulb in the ordinary course of nature would have been dead and gone by this time. Then how can it be said with truth that the bulb that has flowered this year has ever flowered before? Or with what truth can it be said that the bulb that has flowered one year will ever flower again?—DUNEDIN.

NOTES AND GLEANINGS.

At the last meeting of the Floral Committee of the ROYAL HORTICULTURAL SOCIETY a silver Davis medal was recommended to be given to W. H. Michael, Esq., not "Micholl," as published in our report. In connection with these meetings we cannot overlook the apparent anomaly, that while all the collections of the nurserymen have the exhibitors' names, &c., attached, the private collections are exhibited under numbers only. Surely if the names of half of the exhibitors may be attached to their productions those of the other half may be similarly given. Mistakes in reporting would then be less likely to occur, uniformity would be secured, the meetings would be more interesting to visitors, equally fair to exhibitors, and more generally convenient to all concerned.

—The Council of the Royal Horticultural Society have decided upon holding a PROVINCIAL SHOW this year, and as soon as the necessary preliminaries are arranged due notice will be given.

—We have received a copy of the proposed schedule of the CARNATION AND PICOTEE SHOW which is to be held in London in July next. There are ten classes, and the value of the prizes range from 70s. downwards. A list of supporters is appended, showing that upwards of £40 has been subscribed. Further aid is solicited, and we trust that it will be forthcoming, so that a substantial impetus may be given to the cultivation of these beautiful flowers.

—A CORRESPONDENT writes to us as follows regarding the FLOWERING OF THE LAURUSTINUS:—"Many have remarked on the remarkable profusion of flowers which are being produced by this shrub; but it is not remarkable that while vegetation is earlier than usual owing to the mild winter, the Laurustinus is much later in flowering than has often been the case during severe winters?" We should say it is very remarkable if it is so. What do other observers say on the subject?

— At the suggestion of Lord Alfred S. Churchill the Council of the ROYAL HORTICULTURAL SOCIETY have decided upon affiliating provincial horticultural societies upon an annual subscription of five guineas; and the privileges offered to such societies are: A member's ticket to the Secretary, and twelve single tickets of admission to any meeting or show of the Society in London; also the following medals to be offered as prizes at the shows of the local society—one silver Knightian, one silver Banksian, one bronze Knightian, and one bronze Banksian, so that societies which have not medals of their own will be enabled to offer these as premier prizes.

— **STANDISH MEMORIAL FUND.**—An excellent portrait by Mr. F. Havill has been secured, and is now hung, together with those of Mr. T. Rivers, the late Mr. James Veitch, and Rev. J. Dix, in the Council-room of the Royal Horticultural Society at South Kensington. The ownership of the portrait is vested in the trustees of the Lindley Library, as per annexed letter, who also hold the other portraits, so that should circumstances necessitate it, it can at any time be claimed and removed from its present position, where it hangs by permission of the Council of the Royal Horticultural Society.

"Royal Horticultural Society, South Kensington, June 9th, 1876.

"H. J. Veitch, Esq.

"SIR,—Your application on behalf of the Lindley Library Trustees for permission to hang the Standish portrait in the Council-room of this Society, was laid before the Council at their last meeting, and I was instructed to inform you that they have much pleasure in granting your request.

"I am, Sir, your obedient servant,

"J. DOUGLAS DICK."

A suitable stone and curbing has been placed over Mr. Standish's grave in Ascot churchyard, with the following inscription—

This Stone is erected by a few Personal Friends to the memory of JOHN STANDISH, Nurseryman, Born March 29th, 1814. Died July 24th, 1875.

The Committee think it only right to annex a copy of a letter received from Mr. Gibbs, to whom the erection of the memorial was entrusted, and which speaks for itself.

Standish Memorial.

Albert Gate, Knightsbridge, September 28th, 1876.

"H. J. Veitch, Esq.

"SIR,—The above monument was fixed last week, and out of respect for the late Mr. Standish I have made it in polished granite instead of stone as originally contracted for.

"I am, Sir, yours truly,

"J. F. GIBBS."

— ONE of the most useful of Azaleas for forcing and early flowering is *A. AMENA*, and the greatest improvements on the species which we have seen were those exhibited at Regent's Park in April, 1875, by Mr. Carmichael, gardener to W. Tugwell, Esq., Crowe Court, Bath. To two varieties—William Carmichael, the result of a cross between *A. amena* and *A. Flag of Truce*, and Mrs. Carmichael, a seedling from *A. amena* and *A. Stella*—floral certificates were awarded. *A. amena* was the male parent in both instances. Mr. Carmichael's seedlings passed into the hands of Mr. B. S. Williams, who has, we observed the other day, raised a large stock which he will in due time distribute. The new varieties have the same small foliage as *A. amena* and flower similarly freely, but the flowers are half as large again and are distinct in colour. These varieties cannot fail to be valuable for affording cut flowers and for general decorative purposes.

— In reference to the report of the General Meeting of the ROYAL HORTICULTURAL SOCIETY Dr. Denny writes to us that he wished to convey to the meeting that he "did not believe, if the matter was properly put before the Finance Committee, that that body could well refuse to allow of the borrowed money being refunded out of the Society's current account." Dr. Denny further remarks "that in instituting the Society's provincial shows the Finance Committee refused to allow any of the Society's money being spent for that purpose; and that the first show was carried out through the exertions and personal guarantee of a few spirited horticulturists outside of and on the Council, but with the understanding that the profits (if any) resulting should be allowed to constitute a distinct fund for similar undertakings in future; and this arrangement was subsequently confirmed by the action of the Finance Committee. I therefore maintain that the money borrowed by the Treasurer (Mr. Dobree) from this fund is as much a debt of the Society's as that which was borrowed to meet the exigencies of the Society of Her Majesty's Commissioners, and which has been repaid."

— In the account of Wortley Hall in another column attention is directed to the fact that *ADLANTUM FARLEYENSE* as potted in loam is much more vigorous than other plants which are growing in soil containing more or less of peat. Mr. Ollerhead of Wimbledon, we have noticed, grows this Fern extensively and successfully and never troubles himself about peat, and he has established a large stock of healthy plants in a very short time. It is a question if peat has not been over-estimated in the culture of Ferns; at any rate it is clear that this fine Maidenhair will flourish without it as well if not better than with it. As the period for the repotting of Ferns is arriving it would be well for those who have not a command of good peat to try a mixture of loam, leaf soil, and sand for the culture of these elegant plants.

— A WELSH reader writes, "About this time of the year complaints are often made about *ALTERNANTHERAS* KEEPING BADLY or dying off altogether throughout the winter. That they can be kept in excellent health I had proof of the other day by some plants which were wintered by Mr. Henderson at Thorsby Park. They were in as robust health as ever I saw any in August or September. If Mr. Henderson would say through the Journal how he treats them with such perfect success, he would do a service to the community at large."

— ON January 22nd at the residence of A. R. Whitney, Illinois, was celebrated the 86th BIRTHDAY OF NATHAN WHITNEY, father of A. R. Whitney. The son had, very commendably, arranged a surprise party in honour of his father. They had killed the fatted calf and loaded the table with the delicacies of the land. It had been arranged that the pioneer horticulturists of the state should be present. Four generations of Whitneys sat down to that table that day. It is remarkable that four brothers of this Whitney family still live there, whose ages are respectively 82, 86, 92, and 94. Mr. Whitney is the king of orchardists in the United States. His crop of Apples the past season amounted to 25,000 bushels, and his purchaser of Apples foot up 15,000 bu. He made 2800 barrels of cider and vinegar. His cider is that which is eight on years old. His orchard embraces 165 acres and is about 20,000 trees.

— IN connection with AMSTERDAM EXHIBITION, which was noticed last week, there is to be a Congress. The subjects for discussion will be divided into three divisions—1, Botany; 2, Horticulture; 3, Vegetable Products. The questions proposed to be discussed in relation to horticulture are the following:—What is the best way to organise experimental gardens and horticultural laboratories? The best mode of conveying instruction in horticulture. The permanence of varieties among bulbous plants. The influence of manures on cultivated plants, especially on Hyacinths, Tulips, and Cabbages. The best method of ventilating greenhouses. The influence of coloured glass on the development of flowers.

— THERE is no other leaf of *Pelargonium* so durable, so Fern-like and graceful for bouquets, as that of *P. fernifolium* (?). "Spray" is a word peculiarly appropriate as applied to this leaf, since it is so divided that little else besides the main veins are left. The "Skeleton leaf" is better known. Yet this is as coarse, compared with the other, as the common Samach (*Rhus glabra*) is compared with its cut-leaved form (*R. gl. laciniata*). The leaves are borne upon long slender petioles, and the mid-vein so curves as to give to the whole plant a rounded, almost drooping habit. Yet, though short-jointed and close-growing, the leaves are so slight that a newspaper can be read if held upon the other side of the plant. When used in bouquets these filmy leaves furnish the much-needed bright green without concealing the flowers, and the long petioles reach the water, and are thus preserved quite fresh as long as the bouquet is worth retaining.—(*American Journal*)

— DR. H. HOFFMANN of Giessen has recently published the results of his observations on the formation of HONEYDEW UPON THE LEAVES OF PLANTS, and has come to the conclusion that it is not to be attributed to the aphid or other insects. A healthy specimen of *Camellia*, which afforded an instance of the phenomenon, was found to be entirely free from insects. The so-called honeydew consisted of a sticky colourless liquid, which possessed a sweetish taste, and contained principally gum. This gradually appeared on the surface of the leaves, slowly forming drops on the under side, which dropped down to be continually replaced. The separation of the liquid continued vigorously for some time, even after the removal of the leaves from the plant. Although showing that the appearance of the dew is not attributable to insects, Professor Hoffmann

was unable to ascertain the real method of formation.—
(*Nature*.)

— In a paper read before the San Francisco Microscopical Society Mr. J. P. Moore states that *PINUS TUBERCULATA* can be readily distinguished from other species from the fact that it bears its cones on the main trunk of the tree, giving it a singular appearance, as they are arranged around the trunk almost in a circle. Usually five, though often seven cones compose the circle: sometimes two or three of these circles of cones will be crowded together. A peculiar feature of these cones is their mode of attachment to the trunk. It may be observed that the bases of the cones rest against the bark, and that they are so firmly fixed as to bear the pressure of several hundred pounds without breaking off. These cones appear upon the trunk while the tree is young, and never shed until the tree dies or has been felled, and even then they do not open for a long time.—(*American Cultivator*.)

— THE first number is issued of an important publication, "THE WILD FLOWERS OF AMERICA," by Dr. D. L. Goodale, Professor in Harvard University, with coloured illustrations by Isaac Sprague. The number consists of figures of five species in four plates, and the plates are accompanied by a botanical description together with some gossip about folk-lore, popular names, &c.

THE CULTURE OF PRIMULAS.

The *Primula* being one of the most useful and effective plants for autumn and winter decoration, also for affording flowers for cutting, that it may be useful to state how I produced the good specimens which were noticed in the *Journal* a few weeks ago. They were grown in small 48-sized pots, some of the plants being 2 feet in diameter, each carrying 150 to 200 flowers, some of which measured 2 inches across. I grew two varieties of Mr. Williams's strain—namely, *sinensis fimbriata* and *filicifolia*, white and red.

My mode of culture is as follows:—The seeds are sown in February in shallow square pans. The pans are well drained with crocks, over which is placed a layer of moss. Although the pans are shallow the moss holds moisture for a long time, which is a great point in rearing *Primulas*. The pans are filled with well-decayed leaf soil sifted through a rather coarse sieve, not pressing the soil firmly, but leaving it rough on the surface. The seed is sown thinly and not covered, but is sprinkled with water at about 70°. The pan is covered with a square of glass, and is placed in a stove where it is quite away from the direct rays of the sun. The reason I prefer square pans for seed-sowing is that I find them much more easy to cover with glass than round pans. Very little water is required until the seed has germinated, which I find with this treatment is in about fourteen days from the time of sowing. When the seedlings appear freely sifted leaf soil is sprinkled amongst them. I have often seen the roots incline to come upwards instead of taking to their proper home; hence the sprinkling referred to, which I have found to be beneficial.

As soon as the seedlings are large enough they are pricked off into pans of the same kind filled in the same manner as before, with the exception that a little loam is used with the leaf soil, and they are placed on a shelf in a warm structure. As soon as they have filled the pans with roots, which is about the middle of May, they are potted singly into 60-sized pots, using this time a little stronger compost. The seedlings feel their removal but very slightly, after having been previously grown in leaf soil. They are potted rather firmly. Until this season I was under the impression that the *Primula* did not like firm potting, but I potted these plants when I gave them their final shift as firmly as I should *Parlagoniums*, and I have been well rewarded. About the end of May or beginning of June the plants are placed in a frame, shading them during the hottest part of the day. As soon as the pots are well filled with roots, which is about the middle of July, they are potted into 48-sized pots well drained, using about two parts and a half of good loam, one part of leaf soil, and a half part of two-year-old fowls' manure, adding a little pounded charcoal, and plenty of silver sand. They are afterwards placed in a cold frame, affording them plenty of room for a free circulation of air amongst them. They are syringed slightly after the shading is removed about four o'clock in the afternoon. All the air possible is admitted during the day, and the ventilators are left open about 2 inches at the back of the frame at night. The roots are never allowed to become dry, liberal supplies of water being indispensable to the well-doing of the plants.

After the middle of August a pinch of guano is sprinkled over the surface of the soil once a week, which is of great assistance to the plants, improving the size and colours of the flowers. The flower buds are pinched out until the middle of September, after which time they are allowed to remain and expand. About the end of September or the beginning of October the plants are removed from the frame and are placed on a shelf in a greenhouse. They are in full beauty by the middle of November, and continue flowering freely until the present time with the assistance of a little guano and manure water.—J. PITHERS.

DINNER TO MR. JOHN LEE.

We noticed in our last issue that it was the intention of some friends of Mr. Lee, who were members of the Horticultural Club, to invite him to a complimentary dinner at the Club house on the occasion of his retirement from business after an honourable career of fifty-four years. The dinner took place on Thursday evening last, and was in every respect a most successful one. A very large number of horticulturists met to do honour to their guest, many having come from various parts of the country for the purpose. The chair was occupied by Dr. Hogg, and the vice-chair by the Hon. and Rev. J. T. Do caven. Amongst those present were Messrs. G. F. Wilson, H. J. Elwes, Lewis H. Killick, J. West, Dr. Masters, Rev. H. H. Dombtrain, Herbert Adams, T. Moore, T. M. Shuttleworth, E. R. Cutler, H. K. Mayor, Henry Webb, H. G. Quilter, Smith (Kew), A. F. Barron (Chiswick), Harry Veitch, Bull, McManus, C. Turner, G. Paul, Wheeler, Wills, Deal, Francis Rivers, Matthews, A. Henderson, Charles Lee, Williams, &c. The tables were most beautifully decorated by Mr. Wills with his acclimated taste, who thus desired to show his respect for the guest, and the choicest flowers and plants were lavishly used for the occasion. Mr. L. H. Killick contributed a fine collection of fruit for the dessert. The dinner was of the most *rêcherché* description, and reflected great credit on the manager of the Club.

The toast of the evening, the health of Mr. Lee, was proposed in feeling and appropriate terms by the chairman, who alluded to the historical character of the firm, and how during its long career it had been bound up with the progress of horticulture in this country. He spoke also of his own long friendship with Mr. Lee, and tendered him on his own behalf, and that of those assembled, the right hand of fellowship, wishing him long life and happiness to enjoy his well-earned rest. Mr. Lee, who on rising was received with hearty cheers again and again repeated, acknowledged with much emotion the compliment which had been paid him, so unexpected and yet so welcome, and cordially thanked all those who had been in any way instrumental in paying him this compliment and the many friends who were present, and said that the recollections of this evening would ever remain in his memory. Among the other toasts proposed were the Chairman, by the Rev. H. H. Dombtrain; the Vice-Chairman, by H. J. Elwes, Esq.; the Horticultural Club, by Dr. Masters, &c.

There was but one sentiment expressed by all present, that of unmixed satisfaction at the complete success of the dinner.

SPECIAL SHOWS.

More than one of your contemporaries have made some remarks not over-complimentary about "special societies." One of them cannot see the use of the said societies, unless, perhaps, one for the encouragement of the Potato; and another would like to know what good there is in fostering the separate existence of such bodies as the Carnation, Auricula, and Chrysanthemum Societies. Now, I happen to know that there are many gardeners ready to ask just such a question, and perhaps some amateurs. I answer this question by asking them another—What is the object of cultivating flowers at all? Gardening has been called "the purest of human pleasures" by the sage and the philosopher, and the man who takes a special personal interest in his flowers is the man who derives the greatest benefit from his garden. An Auricula exhibition does good in many ways: it stimulates the growers to put forth all their powers to bring their plants up to the highest state of perfection. They are each eager to stand first in the race, and their flowers are watched and tended with incessant care. All this gives pleasure which is unknown to the man who has not himself run in the race and been first at the goal.

Then there is another pleasure for the growers after the arduous labours of staging the plants: New acquaintances are formed, and old friends meet to talk over matters connected with the flowers in which they are interested; and special shows promote the culture of favourite flowers, and to those shows which have been held yearly for three-quarters of a century we owe the great improvements that have been made in the *Anriela*.

An *Anriela* show in London or Manchester brings growers from different parts of England, from Scotland, Wales, and even Ireland who are growers but not exhibitors. They see the flowers as they may not have seen them before, and to see Booth's Freedom with nine perfect pips, or Smiling Beauty, the fairest of the fair, or some rare old variety like Page's Champion, is worth a journey from Ireland or Aberdeen. Such success has not yet fallen to their own lot, but they will go home carrying many pleasant reminiscences with them, and they will also try to emulate the growers who exhibit at the great show. It is not worth while to dwell on other flowers, the Tulip, Carnation, or Pink; but as there will be three great "special" shows of Carnations and Picotees this year—London, Leeds, and Manchester, it may be worth while to consider whether they "claim any special notice," or whether they have accomplished anything after all. There are others who have been in the field for many years, and who could say much about the pleasure they have derived from the culture of these flowers, and how they have been fostered and improved by the aid of special societies; and some of the old growers, such as Mr. E. S. Dodwell, who grew for exhibition when most of us were headless boys, could if they chose tell us of the good they and their fellow exhibitors derived from studying the habits and characteristics of their plants.

One reason why this matter has been taken up at the present time is the alteration in the arrangements of the Royal Horticultural Society. Growers fancied that no prizes would be offered; and the Royal Botanic Society, who gave prizes for them, have also turned from the Carnation, Picotee, and Pink. Are the florists to blame for espousing the cause of their own favourites? I trow not. They cannot go in for Potatoes, nor will they throw cold water in the faces of those who wish to promote their culture. Mr. K. Gilbert, ever first to espouse the cause of the Cabbage or Potato, has already suggested that the growers take the matter in their own hands, and if they go into the work with the same zeal as the florists there will be no need to trust to seed firms or royal societies. They will find ready sympathisers in the florists, who know from experience the amount of labour to be endured before the work is accomplished.—J. DOUGLAS.

POINSETTIA PULCHERRIMA PLENISSIMA.

MR. TAYLOR (page 123), who can grow the old *Poinsettia* so well, will, I think, be satisfied with the new one another year, if he does not, as so many do when they obtain a celebrated plant, weaken it by an exhaustive system of propagation. I have not been able to "try my hand" at growing the new plant, but my neighbour has, and as he has succeeded and not succeeded, and as I know the "reason why," I can write just as usefully as if I had been the actual grower.

My neighbour purchased two plants of the new *Poinsettia*. Both of them on arrival were, on account of the great demand and rapid propagation to meet it, found to be necessarily small and weakly. The largest of the two plants was encouraged to grow in the best manner possible, and was not permitted to receive any checks either by stopping or deficiency of support. This plant perfected a very good head of eleven distinct crowns. The other and the smaller plant was also grown as well as possible, but was stopped and the cutting was struck. Other cuttings were subsequently taken, and the stock now numbers a dozen plants. The heads produced by these small plants were very poor and unsatisfactory. Success was clearly the result of a luxuriant plant, non-success the result of weakly plants.

Now I do not suppose it possible that small plants purchased last spring could by any course of culture be so vigorous in their nature as were the plants which produced the gorgeous heads which Messrs. Veitch had grown in 1875. I had the opportunity of seeing those heads, and I can only justly describe them in one word—magnificent.

As I am a believer in the dictum that what has been done once can be done again, I am very hopeful that with strong cuttings to begin with, no stopping throughout the season, and

a course of generous treatment, resulting in really vigorous plants, that infinitely better results will be produced in the next than was the case in the past season, and I am satisfied that another year of experience is needed before a just judgment can be pronounced on this closely propagated plant.

The bracts produced by the small plants referred to were not nearly so bright as those on the more vigorous plant and larger crown. When I saw the new variety at its best the colour was decidedly brighter than that of the old species—rich as our old friend is acknowledged to be.—EX-EXHIBITOR.

Your correspondent, Mr. S. Taylor, has, I think, somewhat prematurely expressed his "disappointment with the new *Poinsettia*." I received my plant from the Messrs. Veitch (not a strong one); it was placed with my other *Poinsettias*, and was in due time reported. The soil used was three parts turfy loam, one part peat (Epps'), some silver sand and charcoal. It received the same treatment as the other plants. On its first forming its head of brilliant colour I found the outer or lower bracts rather smaller and not quite so intense in colour as those of the old species; this may have arisen from the plant not being a strong one. It takes fully a month longer after first showing the colour in its lower leaves before its centre or the clusters from its flowers are fully expanded. When so grown it forms a well-filled compact head, which if not grand is very great improvement on the other two sorts which I grow. I consider it very fairly sustains the character given of it, and I think it probable that stronger plants will produce still finer heads.—Geo. W. GREENHILL, *Whist House, Ashford, Kent*.

SELECT FRUITS FOR SMALL GARDENS.

UNDER this heading "PRACTITIONER," on page 98, has submitted a short list of varieties, and has appended the request that those criticising should substitute other varieties rather than add to the length of the list. I think in the main that your correspondent is right in limiting the varieties of fruit for a small garden, but I cannot but think that in many gardens which may be included in the designation "small" a few more Apples than those named might be advantageously included. The subject broached by "PRACTITIONER" is a very important one, and on the whole he has submitted an excellent list—his object having been to select old sorts of established merit rather than to include new introductions.

I will commence my criticism by saying that I think the Grapes and Peaches named are sufficient, and excellently adapted for the great mass of small and medium-sized gardens and for ordinary cultivators—that is, those requiring a succession of good fruit certain of being produced under ordinarily good cultivation; yet I may add in reference to the Grapes that those who have conveniences for ripening Lady Downe's Seedling and Gros Guillaume may also include a Muscat, and I recommend the Bowood or Tynningham Muscat as setting somewhat better than the splendid old Muscat of Alexandria. I mention this because I know there are many who covet Muscat Grapes, but are afraid of planting them on account of imaginary difficulties of cultivation and the fear of not being able to afford them sufficient heat. I repeat, therefore, that those who can grow satisfactorily the two late black Grapes named may grow also the Bowood Muscat, which I think is identical with Tynningham Muscat.

The list of Peaches being excellent, I pass on to Nectarines. "PRACTITIONER" has named two, and two are quite sufficient for many gardens, but those named—Violette Hative and Elruge—are ripe at the same time; in fact they are very nearly alike in all their qualities. For the sake, therefore, of having greater distinctness, and especially as affording a succession of ripe fruit, I should certainly substitute Lord Napier for Elruge. Lord Napier is distinctly early, the tree is a good grower and bearer, and the fruit is large and of excellent quality. It is one of the very best Nectarines in cultivation, and is worthy of a place in the smallest collection.

Figs I will pass over with the remark that those who enjoy this fruit and have not grown Negro Largo have a treat in store. I say this without finding any fault with the two good old sorts recommended—Drown Turkey and White Marselle.

Appropriate, I think, call for no comment, but I must pause at the list of Plums recommended by your correspondent. I cannot conceive any collection of Plums complete without including Rivers's Early Proflic. It is a variety of the greatest value, and ought never to be overlooked by intending planters.

As I must not extend the list I would take out Kirke's, because that good Plum is in use almost at the same time as the still more useful variety Victoria. An excellent small collection I consider the following:—Early Prolific, Green Gage, Goliath, Victoria, Cox's Golden Drop, and Damson. If two Plums only are wanted my choice is Rivers's Early Prolific and Victoria, which are profitable varieties for planting in large numbers.

In the list of Apples "PRACTITIONER" has included both Lord Suffield and Keswick Codlin. I doubt if both are required in a small garden. If for pyramids or espaliers I should choose Lord Suffield; if for standards Keswick Codlin. I make the distinction, because the large fruit of the former valuable Apple is apt to be blown off standard trees in exposed places. I should substitute Cellini for one of the sorts named. Hawthornden cankers in light soils, and I generally prefer Sirling Castle. Bessop's is named—an excellent Apple, but a lifetime before arriving at a free-bearing state. The list given is otherwise good, but a garden cannot be completely stocked with Apple trees that does not include Cox's Orange Pippin. Beauty of Kent for early winter and Gooseberry Apple for late spring are valuable culinary sorts.

In the list of Pears your correspondent has included Beurré de Rance, but in many places that late Pear refuses to ripen; a late sort more certain, and I think more generally useful, I consider Bergamotte Espéran.

The remainder of the fruits named are, I think, well selected. In criticising I have acceded to "PRACTITIONER'S" request by substituting a few sorts for those mentioned in the list referred to, and which is worth perusal by those making a "selection of fruit for a small garden."—A NORTHERN GARDENER.

SQUIRRELS AS DEPREDATORS.

MUCH as I admire the feeling which animates a "WILTSHIRE RECTOR" in his dissertations at page 108, I cannot agree with him as to the harmlessness of his *protégé* the squirrel. For over forty years I have had ample opportunities for observing the habits of squirrels, and know from actual observation that at times they destroy more than they get, and get more than they have any right to. Some twenty years ago I could not account for the disappearance of the Strawberries from an early plantation, but one morning I saw numbers of "Blondins" (I should think two or three generations) hop across from a quarter of Currant trees, each seize a Strawberry, and away to the woods went they, but if suddenly disturbed would take refuge on an old Pear tree which was near. When they considered all danger was over they would renew the attack. I was cruel enough to send them a few messages in the form of shot, and before seven o'clock the next morning I had destroyed upwards of a dozen, and I felt no compunction for the deed. After that slaughter my Strawberries were unmolessted.

I have also had numbers of Apricots, Peaches, Cherries, Nectarines, and Filberts taken by squirrels—Apricots more especially; and, from that part of the wall where "that gardening boy" could not reach were he so disposed. I have frequently seen them nibbling away at a half-ripe Nectarine on the top of a lofty Pine tree, and more frequently picked up a half-destroyed fruit under the Pine or Cedar trees, whichever were most convenient for them. I have also seen them run along the parapet or coping of a wall, and when they arrived at a tree bearing fruit suitable to their palate drop down, take one, and carry it off. I have (much as I dislike steel traps) been cruel enough to bait several traps, place them on the coping, and after securing several of the "graceful" thieves, and scaring others, the fruit was safe from the marauders.

My organ of destructiveness is not very largely developed, but when I have an enemy I feel bound to fight till I conquer, and I consider that when a gardener has produced a crop of fruit that he is equally bound to preserve it.—J. GADD.

MANY years ago I was a mischievous "garden boy," and once stole a Peach from a young and favourite tree then bearing its first crop in a vinery. The owner was naturally greatly chagrined when acquainted with the fact by his gardener—not the fact of my being the culprit, for I kept that knowledge to myself, but that anyone should have been guilty of stealing from that particular tree.

The owner conferred with his experienced and sensible steward, the result was that all the men and boys in the garden were what is known as "carpeted," the carpet in that instance being one of Nature's weaving—the "mossy lawn," beneath the shade of an ancestral tree. The "old man with silvery

locks" then addressed his assemblage somewhat as follows:—I am desired to speak on a matter which to you may appear trifling, but which Lord — regards as serious. His lordship, as you know, is not a hard master, and the value of a hundred Peaches are nothing to him, but that one Peach—the first of its kind which had ripened in his garden—was being anticipated with special interest, and someone stole it. No one amongst you is suspected as being dishonest, and not one of you is permitted to deny having committed what was doubtless merely a thoughtless act. I am only desired to urge on one and all never to take on the sly what you would be ashamed to take openly, for his lordship wants to feel that everyone in his employ is trustworthy and honourable. The one who took the Peach may, if he chooses, admit to the gardener having done so, the gardener having undertaken not to mention the confession to anyone, and in fact is prohibited from doing so to his lordship and myself.

That was the gist of the "old man's" address. It left me very uncomfortable, and after one sleepless night I confessed my fault to the gardener, and I cannot look back to any circumstance with greater pleasure than to the taking advantage of the "conscience clause," and certainly I have never since—in the sense of stealing—taken fruit which did not belong to me.

Shortly after that episode several Peaches and Nectarines were misused from the south wall of the garden, and other fruits were nibbled and left on the trees. Many hundreds of fruits were "stolen," and I was told by the gardener that had I not so willingly confessed my former fault I should have been suspected of the present and greater delinquency. There was a reward of having done right—a good name following the acknowledgment of a bad deed.

Determining if possible to find out the rogues, I decided to pass the night in the garden ensconced amongst the Currant bushes. It was not until daybreak that I obtained "a clue"—a most convincing one. First one squirrel came, then another, until at least a dozen of the "agile creatures" were "trying" the fruit, and carrying away those which separated easily from the spurs. The gardener was told of the circumstance, but was not convinced until he saw the same "little game" repeated the next morning. There was nothing for it but to destroy the robbers, which were mercifully shot, and not cruelly trapped. Many times since then I have known squirrels to have committed great depredations on the Peach walls, having repeatedly seen them carrying off the fruit.

I have read with great pleasure "WILTSHIRE RECTOR'S" humane letters, and I trust he will never cease wielding his pen against heedless pain being inflicted on any dumb animals; but I cannot allow "that gardening boy" being made the scapegoat for the pilferings of "those graceful creatures" the squirrels.—AN OLD GARDENING BOY.

AMOUNT OF WATER IN TREES.—FARMERS and gardeners have often observed, and the fact is referred to by Lindley, that during cold weather the branches of certain trees are sometimes so much bent down as to obstruct passage below the tree, but that with the advent of mild weather they return to their former positions. In investigating these phenomena Professor Gelezou observed that they depend not only upon temperature but also upon the humidity of the air, and he undertook, therefore, a series of researches to ascertain the amount of water contained in different parts of the branches under various atmospheric conditions. The first part of these researches (not yet published) proved (1) that the amount of water increases in each branch from its base to its summit; (2) that the bark of the Larch throughout the year contains more water than the wood; and (3) that in Conifers the upper part—i.e., the part above the pith of a horizontal branch, contains always more water than the lower part, whilst in other trees, as, for instance, the Birch, the conditions are reversed; altogether, that Conifers and Dicotyledons seem to possess opposite properties as regards the distribution of water in the tree. Further researches, published now in full (*Bull. Ac. de St. Pétersb.*, vol. xxii., No. 3), introduced new elements into the inquiry—namely, the varying amount of water in the bark and the wood. It appears from these researches that humidity of the wood and dryness of bark have a constant relation; that in certain trees (Fir and Maple) the wood remains throughout the year drier than the bark, while in others (Birch and Aspen) this is the case only during a part of the year, the conditions being reversed at other times. The re-

lations between the humidity of the bark and that of the wood are so constant that a useful classification could be based on them. It appears, further, that the smallest amount of water contained by the branches of certain trees, as, for instance, the Fir, is observed during the season when the vegetation is in fullest vigour, and that this circumstance, as well as some other important facts, is in close relation with the development of leaves. Altogether the researches, which are yet far from being completed, promise to disclose, and probably explain, a variety of very interesting facts.—(Nature.)

PRIMULA INTEGRIFOLIA.

SINCE attention has been more particularly directed to old species of garden flowers, this somewhat rare *Primula* has been required for. Only a few of the modern gardeners know this plant, and fewer possess it. Not that sufficient time has not

elapsed for its increase, for it was known and was probably more plentiful in Phillip Miller's time than it is now; at any rate it is alluded to by that old author, who quotes descriptions of it by Haller, Scopoli, Jacquin, and others. It is a dainty gem from the Swiss, Pyrenean, and Austrian mountains, having somewhat of the habit of *P. auricula*, but flowers perhaps less freely than that species. In foliage it is perfectly distinct. The colour of the flower is a deep rosy red, with a white centre and yellow anthers. It is a hardy plant, but cannot endure stagnant water, and is worthy of the shelter afforded by rugged stones or rockwork. Mr. G. F. Wilson is successful in the culture of many delicate alpine plants, by protecting them with stones set on edge, forming triangular recesses for choicest species. Mr. Matthews of

Weston-super-Mare has also provided earthenware protections, which cannot fail to be useful for "old and rare" alpine plants of low stature and subject to injury by prolonged wet. A plant of *P. integrifolia* was figured in the "Botanical Magazine" more than half a century ago from a specimen raised by Mr. Loddiges from seeds which had been sent from Austria. It is readily increased by offsets of the roots, which are produced freely; the plant, in fact, may be said to grow more freely than it flowers, still it is a "dainty alpine gem" worthy of notice.

WORTLEY HALL,

THE RESIDENCE OF EARL OF WHARNCLIFFE.

THIS grand old English mansion is situated in the midst of a thickly populated district, nine miles from Sheffield and five from Barnsley. The Hall is a fine stone mansion, which covers nearly an acre of ground, and is encircled by verdant lawns and thriving shrubberies. The Earl of Wharnccliffe is the owner of other estates, as extensive as Wortley, in Scotland and the north of England, besides possessions in Cornwall and elsewhere; but the Wortley estate is the most valuable, on account of its coal and other minerals. In the seclusion of the parks, which extend around the Hall on every side, the stranger would never suspect that he was in the centre of one of the most densely populated industrial districts in England, and that underneath the very ground on which he stood there was for miles in all directions a working population, day and night, nearly as numerous as that above ground. Though none of the pit shafts or villages, or even a house, are visible from the Hall, because of the surrounding woods, the pit "workings" are pushed up to within a few hundred yards of it, and

so near the surface do they come in some places that the sound of the colliers' mattocks can be heard from the surface, while the colliers can hear the travellers' footsteps overhead. This is near the "outcrops" however; for in other directions the coal seams descend rapidly to a depth of some 200 yards. Not far off is the fatal Oaks Colliery and Swaith Main, which within the last few years have entombed at least seven hundred victims, besides other explosions, bringing the destruction of human life up to nearly one thousand.

The present Hall is a comparatively modern structure. The original mansion (Wharnccliffe Lodge) was built in 1510 by Sir Thomas Wortley, that he might have the pleasure of hearing the wild duck's bell, a sylvan sound that appears to have been very pleasing to our ancestors. This lodge, a part of which still stands, was at Wharnccliffe Chase, about three miles from the present Hall, and now forms a deer park 1000 acres in extent. Here also is Wharnccliffe Oak Wood, which comprises

about 2200 acres of land, and is said to be the most extensive in England, and Wharnccliffe Crags, the traditional home of the "dragon of Wortley," which ate up "geese and cattle," and everything that came in its way,

"Save the stones poor Jack which
it could not crack,
And you'll find them there on
the hill."

Through the kindness and liberality of the Earl of Wharnccliffe nearly the whole of this vast tract is absolutely free to the public three days in the week, and Wortley station is a regular depot for "specials" during the summer season, bringing thousands from Manchester, Liverpool, and Yorkshire. It is the birthplace of the Hon. Edward Wortley Montague; and the accomplished Lady Mary Wortley Montague, ancestress of Lord Wharnccliffe, spent a considerable portion of her time at Wharnccliffe Lodge,

FIG. 19.—PRIMULA INTEGRIFOLIA.

from which part of her correspondence is dated. She it was who introduced inoculation into this country from the east, and which led eventually to Dr. Jenner's famous discovery of vaccination. Lady Mary first experimented upon her own little son, who was inoculated from a Turk. This boy afterwards became the famous "Turk Wortley," and died, it is said, in the Mahomedan faith. I saw a half-length portrait of this member of the family in his Turkish robes hang in the Hall, and I can say a "perfect Turk" he looks.

From the top of Wharnccliffe Crags, more than 1000 feet above the sea level, the spectator gazes upon one of the most extensive and perfectly panoramic views in England—hill and dale, wood and water here all unite to make one of the most beautiful rural scenes imaginable. Far down in the valley of the Don below the landscape is spread out before you like a map, and away beyond rises the Yorkshire hills, which form part of the "backbone" of England. The crags, as they are called, form a precipitous ledge of rocks some three miles long, and everywhere lifted and rent in the most irregular manner. They remind one of Salisbury Crags near Edinburgh, only that the tops of the ridge seem to have toppled over at its upthral and rolled down into the valley below, which is everywhere strewn with huge fragments of rock, many of them perhaps 50 or 100 tons in weight. Passengers from London to Manchester via the Great Northern railway pass through five or six miles of Wharnccliffe Wood; at the bottom of the valley and on both sides of the line great boulders are to be seen centered in every direction, but they are now green and mossy, and half concealed with Ferns and undergrowth.

With this brief description of the extensive woods, and parks, and crags of Wharnccliffe Chase we now retrace our steps and turn to the modern gardens of Wortley Hall. I

had heard so much of the fame of Mr. Simpson, and knowing his name was a "household word," I had long felt an inclination to pay him a visit, and though it was the 1st of December, one of those pitiless rainy days, nevertheless I was amply rewarded with what I saw. Dull December is not the most favourable month in the year for visiting garden establishments and giving reports thereon, but at a place like Wortley there is always some interest and something to be learnt and remembered. Having left the picturesque scenery of Wharfedale Chase we now reach the kitchen gardens. These are said to be three acres in extent, and a good portion will be covered with glass which at present is rather limited for the wants of such an establishment, but vegetables and salads appeared to be abundant. The gardens stand on elevated ground, about 700 feet above the sea level. The climate is cold, and the more tender fruits often suffer. The gardener's cottage is situated at the west end of the garden near the

ranges of glass houses, and starting at this point we will begin with the first block, which is 130 feet long and divided into four divisions, three of which are vineries. The first house is 30 feet long, 16 feet wide, with a hipped roof. All the Vines are Muscat of Alexandria. The fruit was ripe early in August; several bunches that were still hanging would weigh from 3 lbs. to 4 lbs. each. The Vines were planted in 1867 4 feet apart, and there are two rods to each Vine. In this house the wood was strong, short-jointed, with large round prominent buds. What little foliage was left on the Vines was thick and leathery, and it bore no traces of having been in the least degree infested either with thrips or red spider. At the winter cleaning of the houses the Vines are never dressed, nor is any of the loose bark removed from them. The second house is also 30 feet by 13, and planted with young Vines. Of the sorts I noticed Black Hamburgh, Gros Colman, West's St. Peter's, Royal Muscadine, Buckland Sweetwater, Golden Queen, which

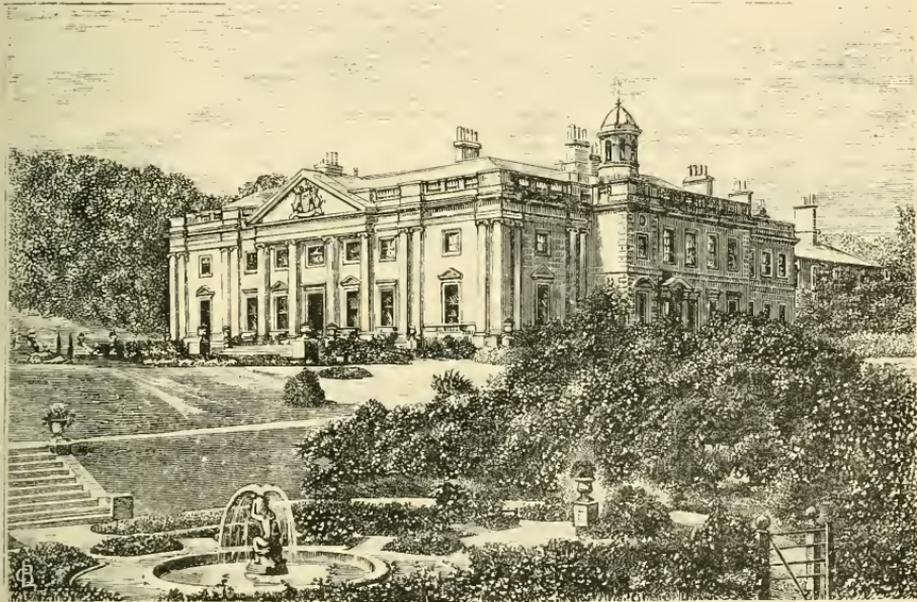

Fig. 20.—WORTLEY HALL.

will remain a lasting memorial of its skilful raiser; Duke of Buccleuch, Vienna's Black Muscat, which has not proved so good as the Muscat Hamburgh, which it was in all respects to supersede; and the Golden Champion, the wood of the latter being twice as strong as that of any of the other Vines. While so many gardeners give the Golden Champion a bad character, Mr. Simpson has succeeded in producing some splendid bunches of this variety. The house was filled with store pots of succulents for the summer flower garden. The third house contained Vines in pots, of which I counted sixty just pushing into growth, and from the manner that they were breaking they promised an abundant and useful crop of fruit. Generally it is found difficult to excite pot Vines before Christmas unless they have been prepared for the purpose the summer previous; but these appeared to break as freely the first week in December as if it had been the middle of February. Besides the Vines in pots there were large batches of Azaleas, Roses, Lily of the Valley, &c., for early blooming. The last house in this range was used for miscellaneous greenhouse plants, and contained good specimens of Azalea, Camellia, Roses, Heath, Epacris, Pimeles. From the roof was suspended streamers of Tacsonia Van-Doixemii, Lapageria rosea, L. alba, Marcial Niel Rose, and Acacia Ricana, a most useful plant for the purpose. On the back wall was a large Rose of Souvenir d'un Ami. It is a most fragrant Rose, and trained against the wall under

glass it affords a handsome flower for the button-hole nearly every day in the year.

Leaving this block of houses we next entered a vinery 50 feet long. It was formerly in two compartments, but now both divisions are thrown into one. The Vines in one half of the house are planted in the centre of the inside border. They are taken to the roof and then allowed to form two branches; one is trained up and the other down the roof. They have been planted about six years, and though they were only intended to remain for two or three years, yet, having done so well, they have been allowed to remain undisturbed. The Vines which previously occupied the house were started into growth about Christmas, and by the end of June all the fruit was gathered, the old Vines cleared out, and these young Vines planted in a new border. As soon as the roots were set at liberty and entered their new pasture the Vines grew with great rapidity and made strong canes by autumn. The following season they carried a heavy crop of Grape, and have done so each returning year. They are chiefly Black Alicante and Lady Downe's, and when I saw them they were such as either Mr. Simpson or any other gardener might be proud of. This is a simple way of renewing a house of Vines without losing a crop. The next house was formerly set apart for Pines, but is now used as a plant house. In front of these houses I noticed a long border full of Lettuces about three parts grown, covered with

temporary lights and in the highest state of luxuriance. They were sown about the end of July, and when large enough to handle they were planted in rows 7 inches from each other and 4 inches apart in the rows. The sort—for there was only one—was Hardy Hammersmith. There were upwards of a thousand plants, which would supply the salad bowl for a considerable part of the winter.

Turning away from the Lettuce bed, which was really a grand sight on the 1st of December, we next passed through a small span-roofed house 21 feet long by 16 wide. It is used in summer as a nursery for young Vines that are being grown for forcing the following winter, but when I saw it was filled with a healthy batch of Cinerarias and bulbs for early blooming. Proceeding still onwards we enter the Fig and Strawberry house, 50 feet long. The Figs are grown in pots in an open pit in front of the house, and the Strawberries on shelves at the back. Forcing the latter was commencing, and they are brought in in batches of about four hundred plants at once. The last houses in this range were two upright vinerias 25 feet long each, and about 8 feet wide, with ridge-and-farrow roof. There are two Vines to each house. From the main vertical shoot other horizontal shoots emanate and are trained near the front glass. The fruit was all gathered and the Vines were at rest, but the young growth was somewhat marvellous. It was firm and well ripened, and about the strength of an ordinary walking-stick. If my memory serves me right the roots were in the inside, and combined with skilful culture, Mr. Simpson uses highly stimulating manures.

Crossing the kitchen garden we reached another range of houses. The first is a block of vinerias 100 feet long with Vines trained up the front rafters and along the top of the back wall. They were at rest awaiting their winter pruning. Here the growth was also remarkable for its strength and firmness. All available spaces in the house were occupied with plants grown for some useful purpose, and not the least useful among these was that most valuable plant for winter blooming, *Rhododendron ciliatum*. Beyond were two lean-to Peach houses each 25 feet long and containing two trees each. There were capital examples of Royal George Peach, Elruge and Stirling Castle Nectarine, the latter being found very valuable. These houses were filled with Strawberries in pots in promising condition. Upwards of 1400 are potted for forcing, which furnish ample gatherings from March till the time of Strawberries in the open air. Mr. Simpson finds the most useful for his purpose are Black Prince, Prince of Wales, and Vicomtesse Hericart de Thury. They were grown in 4½-inch pots and were in splendid condition.

Leaving the fruit houses we next reached a range of span-roofed plant houses which run north and south across the garden, and divided into three divisions. The first was for greenhouse plants, furnished with a stage in the centre and benches all round. It is a useful house, and contained a valuable selection of plants. There were semi-double Primulas, Roman Hyacinths, Erietas, Epacris, Epiphylums, Cyclamens, Camelliar, and Daphnes in beautiful bloom. The second compartment was for stove plants, and many of them were suitable for placing in vases. Here we found many of the most popular plants of the day, including some well-grown *Eucharis amaranthica* throwing up a wonderful crop of flower spikes; Crotons, such as *C. Weismanni*, *C. interruptum*, *C. majesticum*, and *C. Veitchianum* in excellent health; equally good *Draconas* of almost every size, shape, and colour. The most handsome for the table was *Draconea gracilis*, a plant of slender foliage and of elegant habit. There were also *Marantas*, *Alocasias*, and many other plants which form indispensable features in a plant stove. I must not omit the Ferns such as the popular *Adiantum farleyense*, *A. gracillimum*, *A. tenerum*, *A. macrophyllum*, *A. ocnium latum*, &c. One thing here is worthy of special remark in reference to the soil used for the Ferns—*Adiantum farleyense* was growing in peat alone, peat and loam mixed, and loam without peat, and those plants grown entirely in loam were twice the size of those grown in any other compost and twice as vigorous. On the roof was trained *Allamandas*, *Clerodendron Balfourii*, and *Stephanotis floribunda*. The third was an intermediate house, and contained many excellent plants. Near at hand was a block of warm and cold pits several hundred feet in length, used in spring for forcing vegetables, and summer for Melons and Cucumbers; but when I saw them some were filled with Tomatoes, Kidney Beans, bedding Geraniums, winter Cucumbers, and Strawberry; and one range contained one thousand nearly full-grown Lettuces.

Turning into the kitchen garden I observed it was well stocked with all sorts of winter vegetables; one flat of Broccoli contained sixteen sorts, or at least sixteen lots; with different names; Beet, Carrots, Saleary, and Parsnips are left in the ground, and the beds covered with leaves to protect the crows from the frost. These roots are found to keep much better in this way than when taken up and stored in sand or soil. Besides the Lettuce in pits and under spare lights thousands were planted in the open quarters. Round the various quarters I noticed many bush and pyramid Apple and Pear trees, and from their appearance I should presume they carried in average seasons tolerable good crops of fruit. I inquired of Mr. Simpson what sorts he found to succeed the best north of Sheffield, when I was informed that of Apples all the Codlins did well; Claggett Pearmain, an excellent desert Apple, has the flavour of the well-known Ribston Pippin; Lord Nelson, a very handsome table Apple; Lord Seaford, fine kitchen Apple; Hawthornden, a good Apple; and Tower of Glensis, an excellent heavy kitchen Apple. Of Pears, Williams' Bon Chrétien, Napoleon, Jargonelle, Beurré Clairgeau, Baronne de Mello, Knight's Monarch, Louise Bonne of Jersey, and Marie Louise. On a south wall was found to succeed the last two named, Glou Morcean, and Beurré Diel. The Cherries on a west wall were in excellent condition. Such sorts as White Heart and Black Eagle ripen at Wortley early in July, and are found very useful for dessert.

We now reluctantly pass out of the kitchen garden on to the spacious pleasure grounds. These cover an area of fifteen acres, and are kept in the most perfect order. The kitchen garden walls on the south side are judiciously concealed by a broad belt of shrubs, including many fine Hollies. Parallel with the wall there is an herbaceous border 700 feet long and 12 feet wide. This border is rich in hardy treasures, and to enumerate all that is beautiful would be impossible. Formerly this border was filled during the summer season with half-hardy bedding plants, but now it is filled-up with a choice selection of hardy perennial plants: it is not only a great saving of labour, but there is something useful for cutting nearly "all the year round." The gem of the border for late summer blooming was *Anemone japonica alba*, one of our very best hardy autumnal-blooming perennials. It produces luxuriant dark green foliage with a profusion of flowers as white as snow. Then there was *Tritoma uvaria grandiflora*, a stately genus of great beauty for broad borders; *Spiraea palmata*, one of the handsomest species of this beautiful genus; *Iberis corifolia*, *Lithospermum prostratum*, *Potentillas*, *Pentstemon*, *Phloxes*, *Dalrympleum*, *Polemonium ceruleum variegatum*, and many others too numerous to mention. The wall was covered with a choice selection of climbers, from the simple *Lonicera arce-roticulata* and the beautiful *Ampelopsis Veitchii* to the gandy *Cratogeomys pyraantha* and the aristocratic *Wistaria sinensis*.

We now pass on to a broad terrace walk flanked by lines of Roses of every hue and shade, and these again backed by stately Hollies. At the terminus of this walk there is a relic of old Sherwood forest—a majestic Oak 8 feet in diameter at its base, and 7 feet through 5 feet from the ground. It has occupied the same position for upwards of a thousand years, and exhibits no symptoms of decay. Turning to the left there is a broad glade 400 feet long and 100 feet wide. It is margined with Cedars, Pinuses, Yews, and the usual ever-greens that are found in places of such importance. From this grand avenue we reach the terraces in front of the mansion.

The flower garden is approached by different flights of steps, and here the scene becomes of the most enchanting character. Many of the beds are large, and bounded by margins of Yews and Portugal Laurels kept low by constant clipping. The climate is too cold for spring bedding to succeed. I much regret I did not see this fine flower garden when it was embellished with its twenty thousand plants. The water was drained from the fountain in the centre, and the basin was filled-in with dwarf common Laurels. On the east side of the parterre is an old conservatory with curvilinear roof. A stage occupied part of the centre, and round the outside were other stages. It was all aglow with *Chrysanthemums* and other bright winter-blooming plants, and was quite a picture of floral loveliness and beauty. Streamers dangled from the roof in grace and luxuriance, the most conspicuous being a very old plant of *Acacia Ricciana*. It is one of the oldest plants of its kind in the country, and it covered a large portion of the roof. This *Acacia* deserves more extensive cultivation, for it is exceedingly useful to cut from; its long pen-

dulous branches (from 2 to 3 feet long), when covered with flowers, renders it useful for various decorative purposes. Turning out of the conservatory we passed down a flight of stone steps into another flower garden, which Mr. Simpson informed me was generally filled with succulents during the summer. It had a fountain in the centre, and was bounded by Ivy, rockwork, and evergreens.

It is no more complimentary to say that the good keeping of the place reflected the greatest credit on Mr. Simpson, for in each department there was the manifestation of superior skill. I am indebted to him for his courtesy in enabling me to see the many interesting objects abounding on this extensive domain.—Q. R.

NOTES ON VILLA AND SUBURBAN GARDENING.

As was stated in "Notes and Gleanings" on page 105, many mistakes are made by planting large-growing Conifers where there is no room for them to develop. Doubtless those who plant them have reason to admire them for the first few years, after which the mistake becomes more apparent, and the great difficulty arises as to which ought to be sacrificed, and many times none are thinned-out, but they are left to grow one into the other, deteriorating in beauty every year. I submit that nine times out of ten the fault is that of planting too thickly, and then not watching the growth of the shrubs sufficiently close and thinning them out at the proper time. If the shrubs are left to become injured they are not easily remedied.

I dislike to see Decidars and other similar commanding Conifers pressed into a limited space where their true character and beauty cannot be attained; rather would I see small compact-growing shrubs planted, which would be more suitable to the limited space, and would increase in beauty year after year. The little lawns are then well kept in view, and the graceful curves by the paths are well maintained, and the background so prominently kept in sight that the following is seen to perfection. I like to see a handsome Decodar standing in the centre of a circular lawn of moderate size, with sufficient scope of grass round it to show it off to advantage, while other parts may be planted with Cupressus Lvsosyriana and others of a similar growth. *Cryptomeria elegans* is a grand Conifer to grow as a single specimen; while there is *Juniperus virginiana*, *J. excelsa* and *J. chinensis*, as well as *J. ericoides*, one of the prettiest and most compact; while among dwarfers growers there is *J. recurva* and *J. densa*, while *Abies pyramis*, a very pretty dwarf grower and almost an undershrub, but it looks well by itself. Thujas, too, always command themselves to any villa residence with small private grounds. Next we come to the common Yew, *Taxus baccata*, and the golden variety, which really look handsome by themselves and are easily kept within bounds. Irish Yews take up little room, but when well grown they are handsome specimens, while as affording contrast is the Swiss Juniper, erect yet compact growth, and always looks well.

It will be seen by the above that there is plenty of choice among dwarf or small-growing Conifers to satisfy anyone, and those named will grow in towns as well as in the suburbs. Those who need dwarfier plants still may plant the common Savin, *Juniperus sabina*, also *J. tamariscifolia*, both very pretty at all times.

I will now mention a few shrubs as commendable for villa gardens. One of the best is the variegated Aucuba, a general favourite in all towns. The *Laurestinus*, too, must not be forgotten; gold, silver, and plain Hollies must be included in the list as famous town plants. Several varieties of evergreen Berberises, such as *B. Darwinii*, *B. dulcis*, and *B. japonica* are all suitable. The *Arbutus*, too, sometimes does well, not forgetting the Sweet Bay and the variegated and green Box. The dark foliage of the *Phillyrea* always looks well, and it is also a robust shrub, doing well in towns. The common and Portugal Laurels may well be mixed among them. The *Eunomya*—the green, silver, and golden-leaved varieties—are handsome shrubs for town gardens.

With the above and a few deciduous plants mixed up with them, such as the large-flowering and Persian Lilacs, some of the *Acacias* and Maples of the variegated kind, the red Dogwood, the white and pink flowering *Thorns*, with here and there a plant of *Yucca gloriosa*, all judiciously planted and the colours blended together, an effect would be produced that would be at once cheerful and ought to satisfy the most fastidious.—THOMAS RECORD.

DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

KITCHEN GARDEN.

We have been forking over some of the ground that was dug or trenched in the autumn in order to get in the spring crops. It is very wet, indeed wetter than we ever remember to have seen it before at this period of the year. When our light soil is

in this state what can be said of wet districts where the soil is heavy? Even if seeds are of the very best quality, it is more than probable that a large portion of them will be destroyed by the wet cold soils. In large gardens, or even gardens that are not large, there is always refuse loam which accumulates from various sources, such as spent soil shaken from the roots of bedding plants which have been transferred from cutting-boxes to pots or other boxes, the surface of Vines or Leafy borders, or the old soil of Cucumbers or Melons. If this is kept regular and sifted it is of great value in such a season as this; a little of it under and over the seeds will make all the difference between perhaps no growth at all and a healthy lot of young seedlings. The seeds ought to have been brought in long before this time, but many delay purchasing until the seeds are required for sowing, and then grumble if the seedsmen cannot supply them at a few hours' notice. For our own part we order early, and take care not only to order from a good house, but also give the best price; bad seeds are not worth having at any price. Some amateurs and young gardeners are also apt to run after novelties to the exclusion of other proved sorts. Now it is quite right to try as many new varieties of plants or vegetables as one can find room for, but it is not wise to trust entirely to them. Those varieties which have done good service must be retained until we are quite certain that the new varieties are better than the old.

We have sown Early Scarlet Horn Carrots, Hicks' Hardy White Lettuce, and the olive-shaped breakfast Radish under the ground vineries. It would have been useless sowing in the ordinary soil, but the fine dry refuse loam, &c. was valuable for covering the seeds. We also planted out the Cauliflower plants which have been preserved in cold frames during the winter; they have grown so much, even with the lights off night and day, that it was certainly better to plant them out. The weather may change speedily to frost, and perhaps cold east winds will try the plants very much; but they have been planted in drills, and if necessary some manure laid over the surface of the ground will keep them safe from injury.

It will now be comparatively easy to keep up a supply of forced vegetables in succession to those that are now going off. Asparagus roots put in a little heat will soon grow up and be ready for use. Sea-sle will readily be forced by placing blanching pots or boxes over the roots, and enough manure or leaves to cause a gentle heat. Succession pots of Dwarf Kidney Beans can be brought on rapidly in any house, but they are better when the pots can be placed near the glass, as the stems are apt to draw up leggy in the early stages of the plant's growth. They like rich soil composed of good loam and a little decayed manure. The leaves suffer much from the attacks of red spider and thrips, but spider will not be likely to gain a foothold upon them if they are frequently syringed with tepid water and they do not suffer for want of water at the roots. If plants are well attended to with water and judicious air-giving they are not so apt to suffer from insect pests as are those which are badly cultivated.

VINERIES.

The late houses have been made ready for forcing in the way that has been already recommended. At many places the fruit is not keeping very well, it could hardly be expected to do so after so much wet and muggy weather. We are now reduced to Lady Downe's Seedling, which have now been cut for two months nearly, and the stalks put in bottles of water. A few berries have become mouldy, but these are promptly removed. The largest proportion of the bunches are almost in as good condition as on the day they were cut, the berries are plump and the footstalks quite green.

There is now considerable improvement in the early houses. When it was observed that the buds did not start freely they were not forced into growth. Now that the Vines show signs of vigorous development the temperature at night of the Hamburg house is 65°, and that of the Muscat house 70°, with a proportionate rise by day. There is now plenty of work tying-down and stopping the lateral growths. Except the leaders the other growths are stopped two leaves beyond the bunches. We are very careful with the tying-down; it does not answer to pull the strong rapid-growing shoots too much down at one time, as they are apt to snap either at the time of tying or afterwards. The seedlings raised by Mr. W. Thomson, also Canon Hall Muscat, have very strong young wood and require greater care than most other varieties. With increased warmth more moisture is required in the atmosphere; the evaporating troughs are kept full of water, and in bright sunshine the walls and paths of the house are sprinkled with water two or three times a day. We have placed fermenting material (stable manure), in the earliest houses, but when the young leaves appear it is very dangerous to allow even a small portion of rank steam in the house, as the leaves might be destroyed thereby, or at least suffer considerable injury. Those who have berries ready for thinning ought to lose no time in attending to it. One who has had sufficient practice in this work can thin-out a sufficient number of berries all at once. It is not possible to do the work

and knead well until of the consistency of soft soap, and plaster this smoothly round the lower parts of the grafts. If the composition should crack in drying the fissures should be closed, excluding air, and the grafts, all other conditions being right, will grow.

FORCING VINES (W. F.).—Follow the instructions of Mr. Douglas in his "Hints" (you may have a aster. good). You may admit a little air at the top of the house, when the temperature rises to 60°, increasing the ventilation gradually as the heat increases, not permitting it to exceed 80°. During dull days you should raise the temperature to 60° by fire heat—that is, when the Vines are in full leaf. The greater the heat the more atmospheric moisture is required. When the Vines are in blossom the air should be drier than before, but not so dry. Such sorts as Black Hamburg usually set well without any artificial distribution of the pollen, but a gentle shake of the Vines can do no harm, and may possibly be beneficial.

PLANTING HYACINTHS, &c. (N. B.).—Hyacinths after being grown in water seldom flower the year following after having been planted out, but those which have been grown in pots are useful for flowering in the borders during after years. They do not, of course, produce spikes equal to those from newly-imported bulbs. In order to have them as good as possible the spikes should be cut immediately the flowers have faded, and the plants should be placed in a light place under glass and be watered regularly until the second or third signs of decay. Hyacinths are often much injured after flowering, either by being suddenly exposed to frost or by ceasing to apply water, so that the foliage cannot be properly matured. We are pleased to hear that you Roses afford you so much pleasure, and we shall be glad to say aid you can render in making our national flower still more popular.

WOOLLY INSECT (Mr. Llewellyn).—There was no insect in the box. Many of the white downy secretion, such as the common American Apple blight, the Larch leaf-miner, and the Beech-bark species. There are also several species which are found at the roots of various plants, as the Rhizobius Helianthemi on the Jerusalem Artichoke tubers; the Lactico-rhizobius Helianthemi on the Jerusalem Artichoke tubers; the Lactico-rhizobius species, Rhizobium Lactense, and several others. Whether the one which has injured the Anemone roots is identical with the one of the other species, we cannot determine without seeing specimens, but we should consider it most likely to prove a distinct species.—I. O. W.

SHOWING SEVILLE LONG-POD BEAN AND R. MACLEAN PEA (A Young Amateur).—The Beans should be sown the second week in April. The Pea should be sown sixteen weeks before the time required to be ready for use, the Beans about a week, but the waterer will make a difference of a week to ten days in the coming-in of the crops.

ASTERS FOR EXHIBITION IN AUGUST (Idem).—Sow the seed at the end of March or early in April in gentle heat, placing the plants on, and planting out at the close of May or early June.

PINE-APPLE MANAGEMENT (Eight-years Subscriber).—The treatment you are giving four plants is the correct one, and ought to cause the plants to show fruit shortly, they being in good condition. If they show in March you will be able to have the fruit ripe by the time required for exhibition.

ALTERNANTHERA (An Old Reader).—The plants should not be kept moist and encouraged to grow by an increase of temperature, potting them (if required) in equal parts of turfy loam and leaf soil or well-decayed manure. By a brisk moist heat you will insure growth for cuttings, which should be sown in a hotbed and grown-on, hardening well off before planting out in early June.

LOBELIA DEFIANCE AND LUCOPIPTON BROWN (Idem).—Any of the nurserymen advertising in our columns could supply them or procure them for you. We cannot recommend dealers.

RAISING BEDDING PLANTS FROM SEED (Kittie).—Phlox Drummondii will bloom for a long time, and is very fine for beds; Tagetes sicula's pinnata is a fine yellow; Ageratum Imperial Dwarf, lavender; Senecio elegans var. double crimson, lilac, purple, red, and white; the Seedling annuals, var. Verbenas may be had very good from seed and in decided colours, as scarlet, blue, and white; also Verbera venosa, purple, all of which require the treatment of half-hard annuals. Violas will also flower well if sown early. Helixwegii is too variable in colour for your purpose. Lobelia, Golden Feather Freyriana, and Petilla which you name, also crimson Beet, are suitable, in addition to which are Saponaria calabrica and var. alba, and Nasturtium King of Tom Thumbs, scarlet and golden. A hotbed is usually freely used in a week to ten days.

WINTER CHERRY, &c. (Idem).—Cut down the plants; they will root more freely than young plants. Give the *Dryopteris* specimens more liberal treatment, rich soil, and it will root in the winter. The *St. Paul* and *Liberal* for planting Gooseberries is 5 feet; 12 in. in poor soil, 6 feet in rich.

DESTROYING AMERICAN BLIGHT (A. D.).—With a fine brush paint the affected parts of the Apple trees with paraffin. It kills the blight and does not injure the trees. We had a choice tree in a pot, and ordered one of the men to apply paraffin to the affected parts; he did so most effectually by painting the tree all round, including the trunk, and the blight altogether. Injured in the least, the buds are all right, and there is now no trace of the woolly pest.

RAISING GLADIOLUS FROM SEEDS (L. H.).—Sow in March and place the pots or boxes in a hotbed. In two weeks the plants will be up, when a fair supply of air should be admitted to the frame. Entitle more freely as the plants attain strength, and by the end of May or June the light altogether water freely during summer, and when the leaves begin turning yellow withhold water gradually, and altogether when they are quite yellow. The bulbs at the end of the season will be found from the size of a pea to a good-sized filbert. They will nearly all flower the following year.

GLADIOLUS CULTURE (A Constant Reader).—No mention of locality is made, and a good deal depends on this as to the period of sowing. In the south of England the best period of the bloom is from August 15th to 25th. It should be recommended that the bulbs be left where they are, notwithstanding their signs of growing, until next month, and then be planted deep, say 6 inches, and gradually raised up to the surface of the soil, by means of a spade. Some kinds, such as Shakespeare and Adolphe Brogiati, are very early, and others, such as Phoenix, sate that they are useless for exhibition.—D. Deal.

CULTURE OF JUSTICIA CARNEA (Constant Subscriber).—As soon as cuttings can be obtained insert them in sandy soil and place in a brick moist heat, say 6 inches, and gradually raise up to the surface of the soil, by means of a spade in small pots in a compartment of loam, leaf soil, and peat, and replace in the frame until established. When in free growth stop the plants, and before the roots are matted report into 5-inch pots, placing the plants near the glass in a

stove. Stop the shoots again to induce bushy plants, and shift as soon as the roots show through the bottoms of the pots into pots 8 inches in diameter, using loam and decayed manure. After the middle of June the plants may be placed on ashes in a frame, keeping somewhat close. All the shoots may then be stopped again. The pots must be well drained, placing over the crown some flaky manure or moss to keep the drainage free. The soil must at no time become dry, and when the pots are filled with roots copious supplies of water will be necessary, giving weak liquid manure twice a week. Young plants should be established every year, destroying the old plants after cuttings have been struck. Frequent stoppings, good drainage, plenty of water, and a warm and moist atmosphere, are the essential points of culture to be attended to.

POTATOES FROM ONE POUND OF SEED (St. Edmunds).—Mr. Pink, gardener to Lord Sondes, Lees Court, Faversham, has grown 672 lbs. of Ereka from 1 lb. of seed. The seed tubers were cut into 121 sets, and were planted each yard apart on the 3rd of April in deeply-dug and well manured ground, in which the following compost had been incorporated—ten bushels of wood ashes, one bushel of soot, two bushels of caustic lime, and ten bushels of leaf soil; 4 lbs. of sulphate of ammonia, 6 lbs. of sulphate of soda, 19 lbs. of nitrate of soda, and 10 lbs. of sulphate of potash to twenty perches of ground. When in full growth the crop was top-dressed with 50 lbs. of superphosphate of lime. Each eye of a Potato was made to form a set. Send ten penny postage stamps to Mr. Pink, and he will return you a pamphlet on this fancy mode of Potato culture.

ROSES AGAINST BRICK WALL (Copper).—The white inflorescence from the mortar will not injure the Rose trees. It is salt-pest.

PEA HOBDELS.—J. A. and Others will send the sizes and prices of these were advertised.

SEVERAL VARIETIES OF CHERRY (C. G. R.).—Red: Leicester Red, Ivory's Nonesuch, Manchester Red, and for a dwarf sort Carter's Incomparable Crimson. White: Wright's Grove White, Veitch's Solid White, Dixon's Mammoth White, and for a dwarf grower Incomparable Dwarf White.

POULTRY BEE, AND PIGEON CHRONICLE.

POULTRY AND BIRD NEWS.

The whole of Mr. G. S. Sainsbury's far-famed Black East Indian Ducks have passed into the hands of Miss Brown, Chardleigh Green, Chard. The variety has lost an enthusiastic breeder, but we hope his great successes will follow the birds to their new home.

Mr. Cresswell and others sued the Committee of the Portsmouth Show the other week for their prize money, and we are glad to say obtained it. We wonder the President and his companions allowed the case to go into Court, for the result must have been certain, especially as they had so recently lost a similar case when sued by the Hon. and Rev. F. Dutton only a few weeks ago.

We mentioned the other day the illness of Mr. T. P. Edwards of Lyndhurst. We now learn that the whole of his stock of White-faced Black Polecats have passed into the hands of Mr. Norwood of Salisbury.

There is to be a Show of Poultry in the Winter Gardens, Bournemouth. We have a copy of the schedule. It seems almost a fac simile of the one issued by Weymouth in the summer, and we hope this Show may be as well managed and as great a success as was that. We doubt, however, the wisdom of the numerous chicken classes, as by the date of the Show many of the birds can be fourteen or fifteen months old, which will probably cause some confusion however sharp the Judge may be. The names of the Poultry and Pigeon Judges are not announced, but we understand they will be Messrs. Hewitt and Esquaint, while Mr. Billett will take the Pigeons. The schedule seems to be carefully drawn up and the prizes liberal. We have also a schedule from Nottingham, where the classes are arranged on the single-bird system. The prizes are good with a low entry fee, while most breeds are well provided for. We can find the name of no Judge announced, which we regret.

There is to be a "Great London and All-England Rabbit Exhibition," on April 18th and 19th. The Show is to be held in the Moutpelier Assembly Rooms, Walworth, and there are to be twelve cups awarded. As the prize money is, we understand, generous, we hope to see a large entry. The Secretary is Mr. Jennings, 88, Sumner Road, Peckham, S. E.

We hear there is a Langshan Club on foot, members of which may on election pay 2ls. or 10s. 6d. each as they choose, but only those paying the larger sum can be on the Committee. The enthusiasts who are trying to start this breed are Mr. Nunn of The Lodge, Barton, Cambridge, and Major Cread of the Manor House, Durrington, Worting. We understand two dozen or more gentlemen have already joined this proposed Association.

The Wild Fowl Preservation Act, 1876, came into force last week, which protects Woodcocks, Widgeon, Teal, Snipe, Plover, Wild Ducks, Wild Geese, Curlews, Searkars, Sandpipers, Godwits, Greenshanks, Ruffs, Shovellers, Stonehatch, Spoonbills, Dunlins, &c. The Blackcap was seen on February 2nd in Surey, which is an early date for the arrival of this migratory bird.

A periodical sale of Poultry, Chickens, Dogs, &c., has been opened in South London. The mart is in Bysson Road, Cam-

berwell, and the auctioneer is Mr. Such. We should think fanciers in that neighbourhood will find this a useful means of sale, situated as the rooms are in so densely populated a part. The first sale was well attended.—W.

AQUARIUM POULTRY SHOW.

Among all the modern improvements for giving enjoyment to man, the now fashionable Winter Gardens rank high. It certainly is pleasing to find shelter from the open parks on windy days in a well warmed garden under glass, where strains of popular music are heard, and the exquisite odours of spring flowers and the colouring of varied and ornamental stove foliage plants mingle pleasantly and kindly for our gratification. This week is added to those charms in the Winter Garden at Westminster a poultry and Pigeon Exhibition for the United Kingdom. From Ireland, Scotland, and Wales; from the busy towns of Birmingham, Manchester, and Liverpool; from quiet country homes in inaccessible districts, came in the baskets on Monday evening, succeeded by their owners on Tuesday morning to enjoy the well-ordered *menu* of Messrs. Cotton & Custance. It is difficult to arrange for a show on so large a scale, and this must account for the spare entries in many classes; and again, many have by now had their eyes opened, and having learnt the locale of most winning specimens perhaps dreaded the *recherche* of Bristol, Birmingham, and Wolverhampton awards, among which their own birds may not have found places, and so kept their birds at home. The quality, however, embraces most of the choicest winners extant; and fashionable London, already domiciled for the season, has had an opportunity, amid the odours of hyacinths and the bright colours of tulips, of seeing a poultry show under exceptionally good circumstances. The Pigeons alone were well worth a visit. On Tuesday the arrangements seemed very much behindhand, and the cards were not up on many pens when we left at 8 p.m. We understand, however, that Mr. Bilet and his staff only got into the hall on Monday evening, as a concert was being held, consequently the work must have been severe; anyhow, at 3 p.m. Pigeons and poultry were without water and food, and cocks back to back were fighting between the bars of the pens. This seemed bad, but matters gradually improved as the afternoon wore on. We still, however, say the cards should have been put on far more promptly, for several fanciers from distant counties went home again quite ignorant as to what their birds had done. The greater part of our report for this reason we must defer until next week, only giving now a few particulars. The two Dorking cups went to Mr. Parlett's Coloured cock, and to Mr. Cresswell's Whites. Mr. Proctor won the Cochin cup with a good Buff hen. Spanish and Poland were magnificent, Mr. Finchwood again pulling-off the Poland cup with his Blacks. French were poor, save for the Houdan hens of Mr. Vallance and the first Crève cock. Brahmas were moderate, Hamburgs excellent, and the Bantams too were good. Among them we noticed a superb pen of White Rosecombs, as good a pair as we have seen for a long time. The Waterfowl were a fair collection, the Rouen Ducks bring especially fine.—W.

THE PIGEONS.

Poultry and Pigeons at an aquarium; well, this is indeed strange! Birds and fish, they don't even come on the table together! I have seen poultry and Pigeons in a drill hall; right enough, too, for Game cocks are the best of volunteer fighters, and among Pigeons there are always Trumpeters. I have seen Pigeons in a palace over and over again; right, too, for the Carrier is, we all know, king of Pigeons. I have seen them also in a tent on the green sward at our summer shows, and the green grass and the Dorkings seemed to suit each other, both being a country look; but I certainly never expected to see birds at an aquarium. It has all together a fishy look.

Now, for the sake of our winter readers, and as the Aquarium is a new place, let me say what it is like. It is a sort of smaller Crystal Palace, a cross between that and the Bethnal Green Museum—not all glass, but brick walls, with a glass arch above, galleries round, shops in parts, and the fish in tanks ranged round the walls, and you see them through the plate-glass side near you. The Aquarium is most easy to get at—no journey out after London is reached. It is within the shadow of the old Abbey of Westminster, Houses of Parliament close by, and the boom of Big Ben is heard as one walks under the glass. It is a London abode, then—actual real London. The day—Tuesday—is, for this soppy dreary winter, quite a respectable day. It does not rain (mark that in your pocket-books), and there is a very old, almost forgotten, acquaintance called the sun actually out, and showing a half-assured but still a shining face.

Next for a good humoured rumble. Everything is sadly behindhand. It seems there was a concert the last night, and the birds were not staged till this morning, and at two o'clock never a card up. I leave then darkness comes, and yet the cards, notably upon the Carriers, Barbs, and Jacobins, not yet up, and no prize list until to-morrow. Hence I must say something about the Show this week and more next. There must

not be such hurry-scurry another year; bad for birds, exhibitors, judges, and reporters. There are over a thousand Pigeons to eight hundred fowls.—Pigeons for news, London and Lindons. Perhaps the Aquarium is the best place yet for a show; the light is perfect, the glassy arch high, but not too high. Another time there must not be pen above pen. With this exception the arrangement is all right, and rows down but not across at the ends is good. Next week I shall hope to go through class after class. Now, only to speak generally, the White Pouters perhaps were a head of the other classes. The Carriers grand, and one Black cock beyond in wattle anything ever before seen. Dragons most numerous and excellent. Of Tumblers the Short-faced, not being Almonds, very superior. Flying Tumblers a capital lot. Jacobins some wondrously long-feathered birds; long in chain, across I mean. Magpies are rapidly rising into great and deserved favour. Here I leave this pretty show for the present; pretty, indeed, as viewed from the galleries, whence a bird-eye view of the birds; but too far for a general and most telling peep.—WILTSIRE RECORDER.

[The awards (although the judging commenced on Tuesday) were not forthcoming at the time of our going to press.]

NORTHAMPTON SHOW OF POULTRY, &c.

The eighth annual Show was held on the 14th and 15th inst., under the management of a new Committee of the newly formed Columbian Society. The entries were good, and the whole placed under the management of Mr. Edge of Birmingham. Mr. Hewitt judged the whole of the poultry, which was no easy task.

Dorkings headed the list, and there were fair classes. The first-prize cockerel very good, but evidently overdone, as his tail fell to one side. In the other colours of Dorkings Silver-Greys and Whites divided the prizes. *Cochins* were very good classes, the Buffs by far the best; but *Brahmas* were to some extent a failure in quality. *French* were very good classes, and in cocks, with one exception, the best were Houdans; but not so in hens, for here were some capital Crèves. *Spanish*, which seem to get a push from this quarter, were very good, the cocks especially fine in face. *Gams*, with here and there a good bird, were a bad lot. *Hamburghs* very good, Gold-angles taking the lead in quality as well as numbers. *Silver-angled* cocks were good as far as the winners went, but the rest only moderate. Hens a good lot. *Pencils* were mixed classes, Silvers taking the lead in both cases, these being by far the best. Blacks were good classes, and very well placed. In *Polish* the entries were uncommonly large. In cocks a Silver was first and Gold second, with a Silver third, many others well deserving a position; and in hens a grand Silver was first, two capital Golds coming in for second and third. Some good Malay cocks were shown in the Variety class; but the second position was awarded to a so-called Loughan. In hens a smart Sultan was first, Malay second, and Minorca third. The Selling classes were rather extensive, and there were some good birds shown in them. *Game Bantams* were not so good as we expected to find them. In the two Variety classes, Sebrights won all the prizes. The entries were upwards of 550.

Pigeons had 450 entries, of which Mr. Gresham judged the Pouters, Mr. Hutton the Selling classes, and Mr. Tegetmeier all the rest. Pouters, White, cocks.—First the Lowestoft winner, clear of the rest, which, however, were very good. Hens a good lot, and the competition close. Any other colour.—First a grand Blue; second a Red, large in crop but thick in girth; third a small smart Black. Hens.—First a Blue and also the second, the third a Red; a fair lot. Carriers had three classes. First in cocks was a Dun; the third, a Dun, we liked quite as well as the second-prize Black. Hens.—First a Black, rather of a light type; second and third were Dun and Black of heavier build. Barbs were mostly noticed, and were very good in both classes. Tumblers.—First a grand Agate, second and third Almonds. Tumblers, Long-eared, were first a Red Bald, second a Rosewing, and third a Yellow Mottle. Foursign Owls were good, and the local birds took the lead; first and second White, and third Blue. English Owls were very good, indeed one Blue cock that was put second was in our opinion about perfect as a Blue. Turbits, with a few exceptions, were not very first-rate. Dragons had three classes, eight out of the nine prizes going to one lot. Jacobins were uncommonly good in all classes. There were several Selling classes, which were well filled.

The *Rabbits* were judged by Mr. Hutton, as also the Cats. Of the former there were 173 in eight classes. The Lops were a very good class; first a Sooty Fawn, 23 by 5, a grand one in all points; second a Fawn-and-white, 21½ by 5, good in all points but smaller; third a Sooty Fawn Duck, large and very pendant in ear, 22 by 4½, several others coming close in measurement. Angoras were also good, the first large and full of very fine wool; second smaller, but also fine in wool; the third losing very little. Many good ones were sadly mated. Himalayans were not a good lot, only the first being of high merit, and this had been bit on the nose, and showed the scar very pro-

THE ADVANCE OF BEE CULTURE.

"B. & W." seems to lament that we have not added much to our knowledge of bee life since the time of Huber. Patience, friend "B. & W.," there is a race of bee-keepers growing up to knowledge who yet will add a few facts to Huber's store, thanks to frame hives and not least to the British Bee-keepers' Association, who, by their great and interesting shows, have done so much to make known modern hives and appliances. There is no gainsaying the fact that during the three years of the Association's existence bee-keeping and interest in the bee has vastly multiplied. Following the metropolitan example, bee hives and honey shows were last year held and associations established at Weston-super-Mare, Worcester, Exeter, Glasgow, Wolverhampton, Grantham, Huntley, Sherborne, Odham, &c., in addition to which the classes for honey were greatly increased at rural horticultural shows; but while the children are in their lusty infancy the parent languishes for want of more members and funds following. I feel sure this has only to be widely made known and help will come, for there wants but a small percentage of the many thousands who have visited the Crystal Palace and Alexandra Palace shows to become members of the Association, and the Committee will be stimulated to grander works in the future. The Association in their shows have never failed in making a profit; entrance fees were always nominal, never more than 1s., and nothing to cottagers. All the officers have worked for love. The prizes and expenses of each show amount to about £160, to which the 250 members' subscriptions, mostly 5s. each, go but a small way. The result has been the Committee have had each year to go round with the hat to make both ends meet, and I fear the same means must be adopted this year to create a prize list. Now let me ask bee-keepers who read my appeal to further the good work by joining the Association without delay. The amount of subscription is optional, need not be more than 5s. per annum, and I shall be happy to give any desired information on the subject.—JOHN HUNTER, *Eaton Rise, Ealing.*

STRAW VERSUS STEWARTON HIVES.

I NOTICE in the letter by "A RENFREWSHIRE BEE-KEEPER" in the Journal of February 1st an answer to Mr. Lowe's inquiry, whether it is the form, material, or construction of the Stewarton hive which enable it to outdo the straw hive. He says that the straw hive in question is the usual dome-shaped, but he does not state what size it was, and which I take to mean the common small round-topped hive which Mr. Pettigrew is doing his best to get replaced by larger hives, the small hives being next to worthless.

I do not consider it quite fair of the "RENFREWSHIRE BEE-KEEPER" to put one of the sort of hive I mean against the Stewarton for comparison, and then publish the difference—viz., "Straw v. Stewarton;" because in my opinion, if it had been an 18-inch Pettigrew straw hive, under the same circumstances it would have shown a very different result, both in breeding more bees to work and gather honey, and having somewhere to put it when it was gathered, for, as a rule, if there is no honey to be had the bees will leave it; and also an 18-inch Pettigrew hive will hold large supers on the top of almost any kind without any fear of them falling off, and there is a large hole on the top ready made for supering.

Next, the super used being of glass made the result of the straw hive still worse; whereas if it had been a hive that would have held a straw or wood super it is very probable that there would have been much more honey stored in it, and not so much would have been consumed in comb-building.

If the "RENFREWSHIRE BEE-KEEPER" would this next season try an 18-inch Pettigrew straw hive against the Stewarton, both equal in health and strength and under the same circumstances, without partiality to either, and then publish the results in the Journal, he would give valuable assistance to bee-keepers in general.

I reared my bees last autumn to five good hives, all of Pettigrew's style. Two of these succumbed to the long cold weather at the beginning of the year, and two I had promised to friends before I lost the others, and therefore I was left with 18-inch hives. My garden is bounded on one side by large ironworks, coke ovens, &c., and the other sides are dotted over with pits and other works, so that my bees have only about one-half the ground to work on that most bees have, and that at some distance off. They had to be fed until the middle of June to keep them alive, and then the weather was grand for them, and they gained in weight and numbers rapidly. They were ready to swarm about the first week in July; but the clover was coming into flower just then, and the weather so good I wanted to keep them in a short time longer, so I put an eke under and a super on the top to hold about 5 lbs., more to prevent them swarming than for filling. About a week after they were so full and the weather so hot I dare trust them no longer, and I expected finding they had gone when I returned home from work every night.

I took the straw super off full on the Saturday afternoon,

then I weighed the hive, &c.; it was 82 lbs. I had a splendid first swarm at night, 7 lbs. good weight, with plenty of bees left in the stock. About ten days after I took a second swarm out, successfully as I thought, when I left them at night; but in the morning there was a nice mess, there had been an accident. Through the weather being so hot it had made the combs very soft, and some honeycombs had fallen down after I left them, the cross-sticks cutting it in pieces as it fell, and all the remaining bees were on the board and out on the front of the hive half drowned in honey. I did what I could for them, and put all I could to the second swarm; but bees when covered with honey cannot clean themselves, and will not stay in the hive, and they were creeping about in all directions, but there was no helping it. It was at the very least 20 lbs. out of my way, besides the loss of a good turn-out. I took 21 lbs. of honey out of it and the 5 lb. super.

The first swarm of 7 lbs. weight of bees were put into an 18-inch Pettigrew hive, and this they filled with combs in eight days after. I therefore put a straw super on it, and in three weeks from putting them in took the super off full and a virgin swarm out of it of 6 lbs. weight, which were put into an 18-inch Pettigrew hive, and fed them for the winter, and three weeks after that I turned the remainder out a good turn-out, and put it into a 16-inch Pettigrew hive full of new combs and fed them for the winter. I took a 5-lb. super and 29 lbs. of honey equal to super honey, all stored in the first three weeks (the weather broke up after), beside filling the hive and super with combs. In all I obtained over 60 lbs. of the finest honey from the stock and its swarms, which in my locality I think no other sort of hive would have beaten. It speaks very well for large straw hives in a poor place, so what will they not do in a good place? and while they do so well with me I can do nothing else but recommend them. They are the cheapest sort of hives for the working man, and answer all the purposes he wants with them. I introduced them to several of my friends last summer, who are now using them, and also the artificial swarming principle.

I try to get as much honey in the hive as I can, because run honey is the sort wanted here, and supers have to be run the same. I sold about 56 lbs. at 1s. 6d. per lb., and if there had been more to dispose of it would have gone at the same price.—P. RAINFORD, *Wigan.*

THE BATTLE OF THE HIVES.

SINCE penning a few remarks under the above heading we have been favoured with two papers by "A RENFREWSHIRE BEE-KEEPER." In the article of 1st February I am reminded of a former controversy on the same subject carried on in this Journal in the beginning of 1873, in which I with other well-known bee-keepers took part, and I am informed for my comfort that my views when then enunciated were considered so latitudinarian and theoretic by the fraternity, "that little support" was accorded to them.

In looking into the Journal of that date I find a keen controversy was being waged on this same question, and with the view of settling it various competitive tests were proposed as between the respective hives named, but very properly no such competition ever came off. On the 27th February of the above year (1873) I wrote an article on the question at issue, in which I very fully made known my views upon the whole subject, and conclusively showed, I think, so far as amount of stores was concerned, that though all the best hives named were engaged in such a contest, a common box taken from a tea warehouse (however ludicrous) might be the winner.

Let us see, therefore, from the following quotations how far "A RENFREWSHIRE BEE-KEEPER" is justified in saying that my views received "little support from the fraternity."

Mr. Abbott writes: "I entirely deny that any merit is due to any class or variety of hive, as a means in itself of acquiring honey." Mr. R. Symington said: "I had a good laugh over Mr. Lowe's fancied contest, and the championing of the tea-chest. There is no doubt as to the result that will follow. That the hive itself, be it straw, wood, or a combination of both, with movable combs or without, round, octagon, or square, has a direct influence upon the net result of honey to be obtained in one season, I for one do not believe." Mr. S. Bevan Fox is the only one who gave forth a dubious utterance. He writes: "I cannot say that I have much confidence in the infallibility of Mr. Lowe's judgment." Then, in summing-up, your excellent correspondent, "B. & W.," thus gives his opinion: "Mr. Lowe's valuable monograph on the subject, happily corroborative of my own opinion, puts the question in its true light," and thus the "best hive controversy" of 1873 was summarily dismissed. On these quotations I make no comment, they speak for themselves.

I do not now revert to the test case of the contest of the straw and the Stewarton—mentioned in the "RENFREWSHIRE BEE-KEEPER'S" garden as narrated in a previous article, but which is more fully explained in his paper of 1st February. By this explanation we have additional light thrown upon the case, and consequently

are enabled more fully to understand not only its character, but also in some measure its results. This explanation is vouchsafed in answer to my query, "Is it by reason of the form, material, or construction of the Stewarton hive which enabled it to eclipse so greatly the straw skep in amassing stores?" The reply of your correspondent is, "I answer in the affirmative. . . . This 'form' the straw hive being the usual dome shape, prevented any super sitting conveniently on it, saving the Abnegon glass, and even to get it placed I had to cut out a portion of the apex with my pen-knife and lashed the glass with cord to the protruding cross-sticks. Then the material of the upper portion of that hive being glass told much against the return. . . . I have heard it estimated by experienced bee keepers in glass-filling that their bees would readily store from 3 to 4 lbs. of honey in wood for every one in glass, and, to crown all, the extra breeding and supering area in the Stewarton over the straw must alike have stimulated the fertility of the queen and the acquisitive principle in the ever-increasing band of her more numerous staff of honey-gatherers."

Now this explanation reveals two things: First, there was no attempt whatever to ascertain the respective merits of the two *hives qua hives* for obtaining honey irrespective of system, a point necessarily implied in this controversy; second, the professed object of the test referred to was to ascertain the merits of the straw and Stewarton on the depriving system, and hence can have no bearing on the question at issue. This being the case we might pass at once for any consideration of it, but even in this light it is unsatisfactory.

"To fairly compare results one hive with another," says "A RENFRESHIRE BEE-KEEPER," "it is obvious that they meet upon a common field." Granted; but there is another equally obvious condition—they must both be treated fairly and alike according to the system adopted. Now, were these two hives in his garden fair representatives of those in dispute between Mr. Pettigrew and himself? and second, was the same system as adopted by him with the Stewarton carried out in all its entirety and fairly with the straw? Let us see. The Stewarton, we presume, was of the form, size, and material considered best by him. The straw, however, was not a straw *à la* Pettigrew, and certainly it has little affinity except in material to the flat-topped modern straw hives in my own apiary and locality. I had no idea that so advanced an apiarian as "A RENFRESHIRE BEE-KEEPER" would have such an antiquated piece of furniture in his apiary; and yet with this dome-shaped antiquated hive, never intended, and having no facilities for supering or working-out the depriving system, we are asked to believe the Stewarton and it were "well matched." There is an ill and appropriate saying with which your correspondent will, I doubt not, be familiar, that "we cannot take the breeze off a Highlandman;" so surely as little can we take a super off a dome-shaped hive. We are told that with all the cutting and carving on the upper portion of the hive, resulting only in a certain aperture being obtained, over which a glass globe of the Abnegon type was lashed with cords to keep it up, and this, too, with the admitted knowledge, as stated, that for every pound of honey stored in this receptacle lashed over the straw, 2 to 4 lbs. would be stored in the wooden super surmounting the Stewarton, and "to crown all" the poor straw laboured under the disadvantage of lack of breeding space below and storage room above. Yet notwithstanding all these drawbacks, this same straw, *mirabile dictu!* stored about 22 lbs. of honey in the glass super, being fully above the quantity which, according to the above estimate, the Stewarton hive itself would have stored had a glass super, in equal fairness, been placed over it instead of a wooden one. The Stewarton, however, was stored below as well, while the straw, curiously enough, was at starvation point; but your correspondent accounts for this "to want of breeding space," which is another unequal condition to which the straw was subjected.

But it is needless to pursue the subject further. Whatever may have been the real cause of the difference in honey results in this particular case, it cannot for a moment be supposed that it was in virtue of the one domicile being of straw and the other of wood.

"A RENFRESHIRE BEE-KEEPER" remarks, that if certain other gentlemen and myself were "more practical," we would see matters in another light. For myself, I will only say if experience and practice could give knowledge I should have a little, and it is because of that experience and knowledge that I have presumed to enunciate my views on this question so unhesitatingly. It has always been my habit, whether in elucidating the natural history of the bee or dealing with the more practical work of the apiary, to form opinions and test principles for myself, and in imitation of Huber, the prince of apiarists, to take nothing for granted which we have the means of subjecting through the crucible of close observation and rigid experiment.

Our common object must certainly be the advancement of sound knowledge in this, as in all other points. In speaking of the different kinds of hives we must do so fairly by all; and it was only when I noticed that our old friend the straw hive (I do

not mean the antiquated dome-shaped of your correspondent, but the straw now generally in use) was being so abused and caricatured as well as to its size and form as to its entire unsuitability to all the ordinary operations of the apiary, and above all as to its necessary connection with the sulphur pit, I did not hesitate to repudiate these disparaging opinions regarding our old friend.

"A RENFRESHIRE BEE-KEEPER" remarks at the conclusion of one of his articles as to his observatory as a kind of hive not suitable for storing honey; I quite agree with him. Such glass or unclothed hives were never intended for such a purpose. They are constructed not for the ordinary purposes of the apiary, but for specific objects—for study, experiment, or pleasure, and therefore do not come within the scope of my arguments nor of any other writer on this question.

That "no such adventitious circumstance as the kind of hive alluded to, wood or straw, can have much or any influence on the amount of stores collected by the bees," is a statement supported by such eminent apiarian writers as Dr. Bevan, Golding, Dunbar, Jardine, Langstroth, Hoish, and Taylor, and many others I might name.—J. Lowe.

OUR LETTER BOX.

VERTIGO (E. R. T.)—It is usually caused by pressure of blood on the brain. The excitement produced by being exhibited would cause it. A tablespoonful of castor oil and a supply of lettuce leaves is the best preventive and remedy.

GLASS FLOWERS (C. S.)—Apply to Messrs. Carter or to Messrs. Sutton, and tell them the size of your ground and kind of soil. Letting chickens out depends up on the weather more than their age. Do not let them out before mid-day unless the mornings are fine.

CANARIES DYING (G. P. H.)—They were not killed by the *Cedrus deodora* buds. The birds cast as we think were cramped, probably from exposure to cold winds.

STEWARTON HIVE (F. J.)—The Stewarton hive is quite dissimilar from the Carr Stewarton, the former being an octagon, the latter a square hive. The Stewarton hive is usually wrought to a depth of 18 inches breeding space—at least, my boxes are 7 inches deep. Two at 9 inches might do as well. Mine are made by James Aliso, cabinet maker, Stewarton, Ayrshire, Scotland, who will supply with bars or frames as required. Honey boxes are but 4 inches deep with seven bars 11 inch wide, all moveable—to all intents and purposes sectional. My colonies are protected by light-wooded moveable covers, top also moveable. The hive is usually wrought with three breeding boxes, and the lowermost removed for winter when vacated by bees. Boxes could be carried cheaply from Ayrshire to Cuck vid Greenock steamer, and I find they had much cheaper from thence than local tradesmen will make them. To 18 inches breeding space, with best colonies, I find it necessary in good seasons to add as many as sixteen supers at one time to keep all honey gatherers at full work, or a total depth of 45 inches. The Carr hive is a smaller, more fanciful net idea.—A RENFRESHIRE BEE-KEEPER.

REMARKS.

- 14th.—Rain in forenoon; afternoon and evening fair but dull.
 15th.—Fair all day but dull; very little sun.
 16th.—Rain in the early morning, but followed by a beautiful day.
 17th.—Very fine all day but cold.
 18th.—Fine but cold all the forenoon; rain commenced about 1 P.M., and continued at intervals all day.
 19th.—Fair though cold all the fore part of the day; very dark at 4.15 P.M., when snow and soft sleet fell; heavy rain at night. A very rapid and sudden fall in the barometer between 9 P.M. and midnight, and the wind very high.
 20th.—Much rain and high wind in the night and early morning, with snow, followed by a very bright sunny day.

About 5° colder than last week. The most remarkable feature was the arrival on the 19th of a sharp storm of wind, agreeing remarkably with the telegraphic warning sent several days before from New York.—G. J. SYMONS.

COVENT GARDEN MARKET.—FEBRUARY 21.

Business has again been flat and prices barely maintained. No alteration to quote.

From observations taken near London during forty-three years, the average day temperature of the week is 48.8°; and its night temperature 32.1°.

FLORIST FLOWERS RAISED FROM SEED.

U NQUESTIONABLY the most important, expensive, and indispensable of flower seeds are those of the plants under notice. No other class causes when inferior so much disappointment, none affords greater satisfaction when superior. Only the best strains are worth growing. Such being the result of much care and forethought—the very best examples in habit of plant with flowers of great size, fine form, great substance, and well-defined colour being selected for seeding, they are not low-priced; in fact I invariably find that a packet of seed of a valuable strain contains but few seeds, causing occasionally perhaps a feeling of disappointment at having so little for the money expended; whilst a lot of seed, whatever satisfaction may be afforded at sowing time, is to my mind suggestive of proportionate annoyance at flowering time. Economy in seeds is not found in cheap articles.

Florist flowers from seed are noticeable for, as compared with named varieties, possessing robustness of growth, dwarfness of habit, and vigorous constitution, combined with a diversity of colour and superior flowers. In brief, to such a standard of excellence has the seed of florist flowers attained, that for general decorative purposes plants so raised are much superior to named varieties continued by cuttings or other modes of propagation. I do not, of course, intend these remarks to apply to such plants as Anriuela, Carnation, &c., grown for exhibition, but I do submit that for a majority of cultivators and general purpose many (and I shall only mention such as are reliable) plants had from seed are hardier in constitution and more floriferous in character than are named kinds which are raised by other means.

Primula sinensis, or Chinese Primrose, is the first demanding notice. The strains of Primulas are now so good, so certain of coming true to character from seed, that no one cares to treat the plants other than as annuals. The plants are distinguished by dwarf robust habit and amplitude of firm-textured, rather deeply-indented leaves, large trusses of flowers borne above the foliage, but not so high as to be straggling; the flowers remarkable for their brightness and intensity of colour, clear eye, large size, great substance, and exquisite fringing. The flowers are not meritorious if under ordinary cultivation they are not 2 inches in diameter. I have a decided dislike to those forms which have a disposition to produce the flowers in whorls. They have a loose straggling appearance, anything but the compactness and firmness of those exhibiting their flowers in a ball-ball.

The varieties are rather numerous. *P. sinensis fimbriata rubra*, purplish red or crimson, and sulphur eye; and *P. sinensis fimbriata alba* are, when the strain is good, unsurpassed; but I also appreciate their varieties following, which are very fine—viz., Florence, scarlet, shaded red; kermesina splendens, bright rosy carmine; Cottage Maid white, striped and spotted carmine; striatiflora,

very like the last, but striped and splashed deep rose; punctata elegantissima, crimson, of great velvety substance, marked with small white dots, and perfect in fringing; and *hincina marginata*, rosy lilac, margined white. All have finely-fringed flowers, and are indispensable for effect where variety is sought for. Russell's Pyramid Red and White are remarkable for having the flowers in a pyramid and throwing them well above the foliage; and the Fern-leaved (*P. filicifolia alba* and *rubra*) are amply furnished with foliage; but the flowers of the last four are not worth much in comparison with those preceding.

I would particularly note the great value of Double Primulas which are now raised from seed. I have some so large and double as to be taken for named varieties, only the greater vigour of plants and their floriferous character soon dispel any such assumption. The colours are white, purplish crimson—the old colour of *P. sinensis fimbriata rubra*; double kermesina splendens (Prince Arthur), carmine crimson; and Double Florence (Prince of Wales), scarlet, shaded red. The doubles often produce their flowers in whorls, giving a pyramidal aspect, and have longer stalks than the singles, hence every pip is available for cutting, otherwise I look upon the whorl tendency as a disadvantage, though there is no denying the beauty of the pyramidal form for table purposes. The doubles are more enduring in a cut state than the singles. A greenhouse without its Primulas deprives its owner of the finest of all dwarf autumn, winter, and spring ornaments.

It is usual to sow at various times for different seasons of bloom, but, except for spring bloom, I consider one sowing sufficient—namely, the early part of April. The pots being well drained and filled to within half an inch of the rim with turfy loam, and decayed manure (reduced to soil by exposure for a considerable time) in equal parts, and a little silver sand, watering the pots before sowing the seed. The seeds are only just or barely covered with very fine soil. The pots are placed in a hotbed—a Cucumber or Melon frame, and kept shaded. The seedlings will be up in ten days to a fortnight, and must be kept shaded, and they are better rather dry than wet, as when the soil is made very wet the plants damp off; also ventilate freely to ensure sturdy growth. Pot-off singly in small pots and return to a frame—a cold one will answer, only keep it close and shaded, but be careful not to overwater or keep so close as to induce damping. After a few days the plants will be established, and should have moderate ventilation and shade throughout the summer. A tiffany or scrim canvas (fine) shading is suitable. The plants are sprinkled overhead every afternoon, and in this way watering is done; but if the weather be dull and the plants not requiring water it is omitted.

The plants are shifted into larger pots as required, which is when they fill with roots, assorting the plants into sizes after they are brought to the potting bench for the final shift, which will be required early in July. The strongest plants have 8-inch pots, the next size 7-inch, and the smallest 6-inch pots. The drainage is thorough,

and the compost used consists of turfy loam and manure reduced to soil in equal parts, with a sixth part each of silver sand and charcoal broken up rather small. The plants are afforded room for development by placing them thinly on ashes in a cold frame, and are duly attended to with water, avoiding overwatering; the trusses appearing before September are removed with a pair of scissors, and at the end of that month a light airy position is given the plants in any house having a greenhouse temperature—viz., 40° to 45° from fire heat. Liquid manure is given at every alternate watering after the pots fill with roots. The plants flower from October until April.

For late spring flowering the seed may be sown in heat in June, growing the plants on in cold frames until October, when the plants should be shifted into their blooming pots, if not already done in September, which is preferable. They require to be very carefully watered and never overhead after the weather becomes dull and wet; say from September to April inclusive, and being careful not to pour the water upon the collar of the plant. The trusses should be removed up to the middle of February for an April bloom, or to within six weeks of when the flowers are required. After the plants have ceased flowering in the greenhouse they will, if they are kept from frost and the spent trusses and old leaves are removed, flower grandly in August onwards if planted out at the end of May or early June in rich light soil, preferably a vegetable one, in a slightly shaded situation. The plants, however, are not worth keeping for a second bloom in pots; young plants are very superior.

CINERARIAS.—These must be of dwarf branching habit, robust and healthy in constitution, and if the strain be good the flowers will surpass in form, size, and colour named varieties. The flowers under ordinary cultivation will not be less than 1½ inch in diameter, and these will have a much better effect than a great umbel of clustered small flowers as starchy and ragged as a wild Daisy. From a well-sorted packet of Cineraria seed we may calculate upon at least half a dozen distinct colours in the progeny—the highest number I have known being ten—and when this is the case the grower may indeed consider himself fortunate, for in not a few instances a majority of the seedlings are selfs, and what is remarkable, blue; indeed I have myself had nothing else at times from a packet of seed. The plants affording blue flowers are when in a small state readily distinguishable by their superlative robustness and the blue tint of their leaves, especially the under side and footstalks. Only the number desired of that colour should be selected from the seedlings. Plants which are weakest in their young state almost invariably afford the best flowers in size, form, and colour.

A word as to double Cinerarias. They must be very different to any I have had to compare favourably with the single. The flowers are too small in size, the petals too narrow and not numerous enough to come up to what we expect of a double flower; indeed the extra internal petals, which constitute anything rather than doubleness, and to which the flower is indebted for its title, detract from rather than add to its beauty. "Blindness" is sometimes alluded to as a defect in Cinerarias, notably of the double. Now I do not remember to have had a plant without florets of some kind, but I have had quite my share of plants the petals which might as well for any good they were never have appeared—in fact some of them, as if aware of their inferiority, could hardly show themselves beyond the calyx. These flowers will unfortunately seed just as freely or more so than those with petals three-quarters of an inch long, and it is the saving of seed from such paled plants that is productive of so much annoyance.

There has been of late a growing disposition to look upon Cinerarias with doubt, it being alleged the progeny were degenerate, and recourse would again have to be had to cutting or offset propagation from named varieties. Such is not consonant with my experience, and will not, I think, be found that of those who will take the trouble to select the best plants and flowers only for seeding. I have known all the best flowers cut by the flower-gatherer, and what flowers were left expected to furnish seed and ultimately plants with flowers equalling them in time to come. No wonder the result is so much blindness and disappointment; but when the best plants and flowers only are selected for seeding I have invariably found that the offspring is marked by, in a majority of cases, superiority. Seed of such will be limited in quantity, and command a relatively higher value than that collected from

plants indiscriminately. There is no plant but what under superior cultivation and selection from for seeding in its best form will exhibit in the progeny decided advancement. Seed of most plants is best when saved by those devoting their care and forethought to some particular class of flower.

In raising plants to flower in winter I sow the seed in April in pans well drained, and filled to within a quarter of an inch of the rim with a compost of three parts turfy loam and one-third of leaf soil or thoroughly decayed manure. The surface is covered with a little fine soil and made level; a gentle watering is given before sowing, and the seed is sprinkled very lightly with fine soil. The seed pans are placed in gentle heat or a hotbed, and kept moist, taking care not to sodden the soil nor allow it to become very dry. The seedlings appear in ten days to a fortnight, and are then kept moist, shaded from bright sun, near the glass, and well ventilated. They are potted-off singly into 3-inch pots when they have a rough leaf and showing another, placing in a cold frame, keeping close for a few days. When the plants are established air is admitted freely. They are shifted from 3-inch to 5 or 6-inch pots before the roots are very closely matted, and from these are transferred to 8 or 9-inch pots. It is necessary that the plants have plenty of room and light—the fierce rays of the sun being broken by shading. They are duly attended to with water, a gentle sprinkling overhead in hot weather of an evening being very beneficial. The plants will be advanced for flowering by early October, but will not expand freely without a temperature of about 50° from fire heat. In an ordinary greenhouse they will flower by January and continue until March. If aphid, for which certinise the plants frequently, appear, fumigate with tobacco.

To flower in spring sow in June, and place in a shaded frame, growing on in the same up to October, and then transfer to a pit or other low structure where they will have plenty of light, and ventilation with safety from frost. Shift into larger pots as required, taking care the balls are not very closely matted before each potting. They will flower from March until June. A slight shade when in flower is necessary, and weak liquid manure may be given at every alternate watering after the pots are filled with roots.—G. ABBEY.

(To be continued.)

JERUSALEM ARTICHOKE.

JERUSALEM is a popular corruption of the Italian name for the Sunflower, *Girasole*, which is literally, to turn to the sun. Artichoke was applied to this vegetable because its tubers when boiled have a flavour like that of the head of the common Artichoke. It belongs to the same botanical genus as the Sunflower, and is the *Helianthus tuberosus*, a native of South America, and is becoming increasingly popular as a culinary vegetable for winter use.

Not many years ago it only existed in a few gardens much as Horseradish existed, being left to occupy the same plot of ground year by year; a few miserable tubers were dug up as they happened to be wanted or could be found, and receiving no systematic or intelligent cultivation. That negligent mode of treating the Jerusalem Artichoke has happily become obsolete, and now the crop is cultivated as a staple winter vegetable in nearly all well-managed gardens. Neither is it limited to the gardens of the wealthy, for as its usefulness became known its cultivation spread into the home plots of every class.

All consumers of vegetables do not, of course, relish the peculiar flavour of Jerusalem, or, as they are becoming popularly known, "Potato-Artichokes," any more than all men enjoy Parsnips; but Artichokes are approved by the palates of most people, and hence these tubers are now offered in considerable quantities in the public markets. The increase of Jerusalem Artichokes has probably received a stimulus in consequence of the periodical destruction of the Potato crops by the murrain, and a desire has been thereby fostered to find a substitute for the indispensable "earth fruit," the Potato; but neither Artichokes nor any other root can be regarded as a satisfactory substitute for the Potato, any more than Cabbages are substitutes for Cauliflowers, or Beans for Peas.

Jerusalem Artichokes are essentially different from Potatoes, inasmuch as the former contain very little starch, while in the Potato starch is a considerable and valuable constituent. But that does not prove that these Artichokes are to that extent inferior to Potatoes in nutritious properties. The Potato has, perhaps, been over-estimated as a flesh-forming vegetable, and possibly the Artichoke has been under-estimated

as an article of food because of its deficiency of starch, but it contains what is closely allied to starch, inuline, also sugar, which is not a component of the Potato.

Taste is sometimes regarded as trivial, but so far from being unimportant it is all-powerful. "Why do you smoke tobacco?" said a gentleman to his coachman in my hearing. "Because I like it, sir," was the reply. The obnoxious nature of the "weed" was then as forcibly as possible placed before its votary, and when it was hoped that some impression had been made on Jehu, his only response was, "I can't help it, sir; I like it," and he continued its use until the end. So it is with vegetables. Potatoes have become popular because people "like them," and Jerusalem Artichokes will also become more popular than they now are as they gradually find their way to the tables of the "masses." There are thousands who have not yet tasted these Artichokes. I have occasionally given a few to my industrial friends for a first taste, and it has been strange indeed if some of the household has not "liked them," and as a consequence I have seen their admission into not a few cottage gardens. But it is not as providing a "dick" that they are alone useful in small families, for they are particularly valuable for "assisting" in soups. Many a family meal might be made more enjoyable by the aid of half a dozen Artichokes, and especially when, as is often the case, the butcher's shop has only a limited share in the proceedings. The full value of these Artichokes for rendering thin soups thicker, and insipid broths toothsome, has not yet become fully recognised. It is not as affording a substitute for Potatoes, but as an adjunct to them that they are recommended, and a few should be planted in many more gardens than is the case at present. They are by no means dainty as to soil, and are productive; their tops also in some places being useful, for horses and cattle will eat them greedily; but what animals will eat Potato ham? The tubers of Artichokes are also liked by most animals, and they are relished by and are beneficial to poultry.

Than Jerusalem Artichokes no crop is more easily cultivated. Rich soil is not necessary, neither is deep trenching; in fact, good crops are produced on comparatively poor and hard soil. If the ground is very deep and rich, luxuriant tops are produced and large ugly tubers, while poorer and firmer soil is promotive of smoother and more useful tubers.

A common mistake is made in planting too closely. Jerusalem Artichokes never yield so well as when planted in a single row, and in this way they are often useful in forming a screen—hiding something which is best out of sight—during the summer months. There are not many gardens where a row of them is not only not admissible, but where their appearance would be an advantage. Look out for such places, and plant in single rows if you desire the greatest yield. If it is necessary to grow in plots on several rows, the sets should not be less than 3 feet apart; in a single row the tubers may be a foot apart. Now is the time for planting, covering the tubers 3 or 4 inches deep. In the cultivation of this crop there is no fear of injury resulting by frost or any disease. It is a poor man's and a rich man's vegetable—a crop, in fact, for everybody who has room for growing it.—J. W.

NEW ROSES OF 1877.

WHEN are we to have any information about new Roses? In the present dull season any information from our great Rose-growers and importers would be thankfully received by very many readers.

Assuredly English-raised seedlings are coming to the front. I have reason to believe that they will receive special attention in the National Rose Society's schedule, which will shortly be published, and to which Mr. Cranston has given such a grand start with his fifty-guinea cup. I incline to think that our English-raised seedlings are beginning to do more than hold their own against the more numerous French productions. Last season produced some grand new English Roses. Will anyone give any idea what we have this year to expect? I see that Mr. Laxton's stock has been purchased by Mr. Turner; in such hands we may confidently expect real additions.

I have before me Messrs. Ewing's of Norwich list of new French Roses. It is impossible to judge much from descriptions or without seeing the Roses growing, but among the sixteen mentioned there appear to be some of promise. Two or three which are really good are, I apprehend, quite as many as can be expected from an average year. A seedling from Barons de Rothchild—M. L. Pernet (Pernet)—appears hopeful,

"retaining the same habit as its parent." The colour is stated to be very bright rose. Mons. C. Tonrier (Levet), deep rose, obtained a first prize at Lyons, as did also Mdlle. L. Poizeau (Levet), Tea, orange-yellow. Another Tea of 1876, Beauty of Glazenwood, if it comes up to its description is likely to prove interesting, being "yellow-gold striped and flaked with carmine, and may possibly prove," we are told "an entirely new genus." A pink Gloire de Dijon (a sport) is also spoken favourably of by the Messrs. Ewing, as even more robust than its still unrenowned parent.—A. C., Brockham.

FLOWER-GARDEN NOTES FOR 1877.

THE latter half of February and the whole month of March are always a busy time with those who have flower gardens to plant in summer. Many kinds of plants, especially Geraniums, may be wholly provided with advantage the autumn previous, but there are others which are best raised in spring, and there are places, again, where there is little or no accommodation for wintering bedding plants, and still they are required in large quantities in summer. It is in cases of this kind, and they are very numerous, where a push has to be made now with propagation. Before beginning this operation, however, there should always be a clear understanding of what is wanted. It is no use propagating a large quantity of one thing when the half of it will not be wanted, and neglecting another of which there will not be enough. This is often the case with plants which are easily raised from seed or cuttings, and I think this may often account for the undue predominance of one plant over another in many flower gardens.

Before beginning to propagate to a large extent, plans of the flower beds to be filled in summer should be drawn out, and the way they are to be planted should be distinctly marked on each bed, then a calculation made of how many plants it will take of each kind to complete the arrangement, and propagate accordingly. This saves all confusion at planting time. Our flower-garden arrangement for the incoming summer was all understood before the new year, and this admits of discarding any unsuitable plants and working up a sufficient stock of those of the most meritorious description. Much might be said about the arrangements of the different plants and colours in the beds, but this is a matter I do not intend enlarging upon, because I find that a combination which one person would call beautiful another would consider the reverse. Some like yellow in nearly every bed to the partial or total exclusion of a desirable amount of other necessary shades and colours; but good taste is always shown by equalising all hues and allowing nothing too "hard" or too "soft" to appear in any arrangement whatever.

Small bed look best planted with one variety of plant, but where there are a number of such beds not far from one another the same subject must not occur too often. As to what colours should go against one another must depend very much on the size, number, and design of the figure or beds. I will only detail one arrangement by way of illustration of what is considered lawful by the regulation of harmony and contrast. Take a small group of five beds, such as may be found in many gardens, with a circle as a centre and four outlying beds forming a square near to it, but with small grass or gravel walks between—plant in the centre of the circle yellow *Calceolaria*, next to this Purple King *Verbena*, outer edge *Dactylis glomerata* or dwarf white-leaved *Geranium*. Centre of four outside beds scarlet *Geranium*, next to this Cloth of Gold or yellow *Calceolaria*, outer edges blue *Lobelia*. It will thus be seen that between the yellow in the centre and the bands in the outer beds there are blue, white, and purple intervening, and no other two colours are alike.

Where plants are deficient for this or any other arrangement no time must now be lost in increasing the number. Those having well-heated propagating houses have no difficulty in rooting any quantity of cuttings without loss, but, unfortunately, many with flower gardens have no such convenience, and are therefore obliged to resort to other means. The next best thing to a house for striking cuttings is a good hotbed. Leaves and long stable litter are the best materials with which to form this. The two should be mixed in a heap together in about equal parts. After lying for about a week turn the whole over and allow it to lie as long again, and then make it into a firm bed about 1½ feet larger in every way than the frame which has to be placed on the top of it. When the frame has been set on build up the sides until they are level with the top. It will be a few days before there is much heat; and a day or

two before any cuttings are to be put into it place a layer of sawdust 8 or 10 inches deep in the inside of the frame. This is an excellent material in which to plunge the pots. When all this has been done cuttings may be put in at once. Have a quantity of clean 6-inch pots, half fill each of them with crocks, spread a few rough leaves over them, and fill up the remainder with fine leaf soil and sand. When the cuttings are choice and tender a layer of sand should be put over the surface of all. As soon as the pots have been filled with cuttings give a slight watering and plunge them at once. All kinds of common bedding plants, such as Verbenas, Iresines, Tropaeolums, Ageratums, &c., root freely under the same circumstances, but after they are rooted care should be taken not to expose them too soon to cold, and do not be in a hurry to "pot them off" after they are rooted, as they are all the better of becoming well hardened both in root and leaf before this is done.

Some propagators pride themselves in making a plant out of every joint and leaf. This may be desirable when anything is scarce, but it is not recommendable. Small cuttings make small plants, and these are of very little use where a large extent of ground has to be filled at bedding-out time. When *Calceolarias* are scarce I find tops dibbled into a cold frame now make fine plants by May.

Many kinds of annuals for bedding may be sown in the open ground, but others must be raised in heat and under glass. These comprise such as *Lobelia*, *Pyrethrum*, *Perilla*, *Stocks*, *Tagetes*, &c. These seeds should be sown in pans or boxes and set in a heat of 60°. Before the seedlings become crowded or drawn they must be transplanted and given sufficient room to develop and harden until they can be finally "bedded out."—S. W.

SEAKALE.

PERHAPS there are no garden crops whereon differences of opinion as to mode of culture, &c., do not exist amongst gardeners. Mr. Abbey on page 116 has referred to Seakale, and has detailed his mode of culture and plans of forcing with considerable minuteness. Yet careful as your correspondent has been to omit nothing of importance, he has yet overlooked two cultural points which, in my opinion, are at least as worthy of mention as the details alluded to. What is the cause of Seakale seed so often refusing to vegetate freely, causing the plants to appear irregularly and over a long period of time? Many old amateurs and young gardeners have experienced this difficulty, the only difficulty in fact, in raising plants from seed; yet Mr. Abbey makes no allusion to it, and does not tell us that the outer husks of the seed should be broken before sowing. If the seed is sown in the spring, and a term of sunny weather follows, which is generally the case, no previous preparation of soil can ensure the germination of the seed and the free growth of the young plants if the seed has been sown with its hard outer envelope unbroken. When the outer covering—the prison wall—of the seed is partially shattered germination is considerably expedited, and the young plants appear above ground as regular as so Radishes.

Next, What is the reason of small crowns? Bad position or poor soil are not the only causes of puny crowns and small "Kale," nor, indeed, are they the primary causes; the great evil is overcrowding. Mr. Abbey gives correct information as to the distances for planting, but that is not sufficient to ensure bold crowns. He tells us that previous to planting the main crown should be cut off to prevent the formation of a flower stem, when other crowns will form and grow large enough for forcing. Yes, they will do so under one condition, but which is (no doubt inadvertently) omitted—namely, the crowns must be thinned out when in a growing state. When the primary crowns of Seakale are severed from the roots a cluster of other crowns form, it may be a dozen in the space of a few inches. It is impossible that these can become bold and plump if thinning is not resorted to. After the stools have grown, say 3 inches, they should be examined and superfluous growths should be removed, leaving from one to three shoots on each stool to form future crowns.

It is only when room is afforded for the development of the foliage that good crowns can be perfected, and without a thinning-out of the growths during the spring preventing overcrowding it is impossible that vigorous crowns can be formed and the best Kale be produced. Yet how often is this simple but necessary practice of thinning crowns overlooked in private gardens! Thinning of the crowns is not neglected by the

market growers. They cannot afford to waste manure in growing a multiplicity of leaves, large clusters of small crowns, and weakly Kale; they must have fewer crowns and good and stout Kale; hence the importance of a timely and sufficient thinning-out of the superfluous growths. This is one of the principal points (and withal is one of the most neglected) in the culture of Seakale.

When stout crowns are produced forcing is a very simple matter. Mr. Abbey writes disparagingly on the old mode of forcing in beds; he calls it expensive, troublesome, and antiquated. Without underrating the advantages of digging up the roots and forcing them in frames and Mushroom houses I have yet an opinion that more and better Kale is produced by forcing in beds than by the "modern" plan of digging up the roots. Seakale pots are cheap, and with care will last a lifetime; but even these are not indispensable, for rough wooden skelton covers or a few sticks placed round and over each stool are sufficient to keep the heating material from pressing on the crowns. In fact there is no mystery about forcing Seakale, nor growing it either. An open position, good soil, and growing the crowns thinly, are the essential points to be attended to.

There is no reason why a few stools of Seakale should not be grown in even small gardens, for the roots, as stated by Mr. Abbey, may be dug-up and forced in any dark place; or if the produce is not wanted early the sun may do the forcing and garden soil the blanching—heaping the soil over the crowns in the form of cones, when the Kale will push its way through, and be of the first quality—stout, tender, and affording an agreeable change for the table during April and May.

—A MARKET GARDENER.

PROPOSED CARNATION AND PICOTEE SHOW.

IT OWES its origin to the fact that, save by this special show, no opportunity is afforded to the cultivators of these flowers for their presentation before the public, neither of the two societies devoted to horticulture offering inducements in the shape of prize, or days of exhibition, suitable for their production, whilst undoubtedly a further incentive to this course of action may be found in an assertion made some time since in your pages—viz., "that florists' flowers were hopelessly at a discount in the south."

When I state further that the proposed show is due directly to the suggestion of Mr. Charles Turner of the Royal Nursery, Slough, and of Mr. Douglas, who has charge of the fine collection at Loxford Hall, I shall have said enough to assure your readers the display will be of great merit and worthy the notice of all lovers of these very beautiful flowers; whilst further, a reference to the subscription list, copy of which I enclose, will show the promoters do not solicit aid without first contributing liberally from their own pockets.

A schedule of prizes which has been proposed, and which the promoters believe would appropriately illustrate the cultivation and development of the flowers, offers ninety-one prizes, including in Carnations collections of twenty-four and twelve, and single specimens in each class. Picotees, white grounds the same; yellow ground Picotees, prizes for collections of twelve and for single specimens; miscellaneous, selfs or fancies (a class usually especially interesting to ladies), three prizes each of twelve blooms; and plants in pots two prizes each for twelve specimens, resulting in an aggregate of 462 specimens, and a money total of £54 16s. The funds thus far contributed amount in round numbers to fifty guineas; a further sum of £15 to £20 is therefore needed to provide the desired prizes and the expenses incidental to the show, and to this extent the promoters will gladly accept of help from any of your readers disposed thereto.—E. S. DODWELL, Hon. Sec., 11, Chatham Terrace, Larkhall Rise, Clapham, S.W.

McLAREN'S PROLIFIC RASPBERRY.

"A MARKET GARDENER" on page 94 makes inquiries whether any growers can detail their experience regarding McLaren's Prolific. In November, 1872, I had occasion to make a fresh plantation of Raspberries. The red varieties planted consisted of Fastol, Semper Fidelis, Carter's Prolific, and Red Antwerp, and for experiment one dozen plants of McLaren's Prolific were at the same time planted, and all the sorts were trained to wire trellises. McLaren's favorite has turned out vastly superior to any of the other varieties named. It is very early, ripening fully twelve days before any of the others, and the

fruit is very large and handsome. It is a most abundant bearer, and is of a very robust and yet dwarf habit of growth. Altogether I consider McLaren's favourite Raspberry a very valuable acquisition. I believe it to be a most profitable variety and well worthy of extended cultivation.—A GARDENER, *Durham*.

THE EFFECTS OF AMMONIA ON VEGETABLE AND INSECT LIFE.

MUCH has been written from time to time on the above subject in your Journal, and I doubt not with profit. In the year 1871 Mr. Abbey detailed his practice with ammonia in dealing with mealy bug, red spider, &c., which was followed by an article from Mr. Wright informing us distinctly that ammonia arising from guano heated in a liquid state would destroy or keep at bay thrips and red spider. In those articles the writers, while testifying to the value of ammonia as an insect-destroying agent, advised also that it should be used cautiously, as an excess of it would be injurious to vegetation. But there is another manure which gives off more ammonia than guano, and is, I believe, more potent and dangerous—namely, horse or stable manure, for when in its first stage of decomposition it gives off ammonia in volumes, which is equally as destructive to vegetable as animal life. In my early vinery there is a pit about 4 feet deep, which every year we fill with stable manure and leaves. In the spring of 1876 we put a quantity of manure fresh from the stable, at the same time sprinkled it well with water, and in a few days it began to steam and give off quantities of ammonia, which destroyed the old foliage of the plants in the house but not the young leaves—a fact I cannot explain.

The plants in the house were a miscellaneous lot, therefore I will describe the effect on each. Ferns stood it badly, as all the old fronds were blackened and presented the appearance of having been burnt or severely scorched. *Polargoniums*, *Echeverias*, *Lobelias*, *Cyrtipediums*, *Contradenias*, *Azaleas*, *Statives*, and *Tricolor Geraniums* all suffered much from loss of foliage, but soon afterwards commenced growing vigorously. *Camellias*, *Cactuses*, *Oranges*, &c., stood in the house without being the least affected. The Vines were only swelling their buds, and consequently escaped injury. We repeated our practice this spring, but with more care, as we put on air as soon as the dung began fermenting.

I have read a great deal lately about the injurious effects produced by fumigating with tobacco, burning sulphur in Peach houses and vineries to destroy red spider, and painting hot-water pipes with sulphur for the same purpose. All these practices have been classed as being more or less dangerous, and extreme caution has been advised in their adoption. Perhaps I should qualify this statement, as fumigating with tobacco is included, which is not very dangerous; yet there are some plants, Ferns for instance, which will not stand tobacco smoke, and Generaceous plants do not like it.

I will now refer to the effects of ammonia on insect life. Mealy bugs, I believe, are not easily killed by the fumes of ammonia. Pickings and squeezing them, or smothering them with paint, as on Vines and the wood-work of houses, are, I conceive, the safest means of destruction. It has been stated that this insect cannot stand water or damp, but where its moisture more plentiful than in a steaming stove? I might almost say that mealy bugs are "waterproof," as I have rolled them through tobacco and soft-soap liquid, and they have afterwards run away as if nothing had happened. The covering of dust, or "meal" as it is called, enables the insect to hid defiance to most liquids, at least when they are applied with safety to the plants. Paraffin oil will kill bug at once, but it will also kill the plants or trees. To become well acquainted with anything is to know its habits from birth till maturity. To this end I have watched this insect in all stages. I will first mention a fair-sized one secreted under bark or under a leaf: soon it will be surrounded with something like very fine cotton wool, and in the process of time the "nest" will be as large as a Cucumber or Melon seed. In this the bug deposits its eggs, not less than one hundred. Now, if the syringe is brought to bear upon these nests much good results, but in a moist stove or vinery the young progeny thrives equally as well as the plants.

As regards red spider I cannot say, like some of your correspondents, that I "never have to do with it," for I have had much to do with it. I find the best cure and preventive is cleanliness, plenty of syringing, and washing the wood, trees and

plants, in winter with strong soft-soap water. It has been said that red spider will not frequent healthy trees or plants. I believe this is a mistaken idea, for there is nothing they like better than healthy pasture. What gave rise to this, was, I believe, they were seldom found on healthy foliage; for trees or plants infested with them, if healthy, will not be long so, but that is no reason why they would rather have an unhealthy pasture. Neglected plants afford them a splendid opportunity for the incubation of their eggs.

Thrips is less hardy than the last-named insect. They can be destroyed by tobacco fumes and tobacco water, and syringing with clean water will destroy their eggs, which are very numerous. Ammonia will also kill them, as I observed many deaths from what I described above about the stable manure. We may write much, and talk much, and be fond about our discoveries of insecticides and such like, still we are the assistants of insect-propagation in our gardens by affording a congenial atmosphere and an undisturbed season for incubation.

I had written thus far when the Journal arrived, and I saw a paragraph calling attention to the use of paraffin against scale and mealy bug. I have not the presumption to question Mr. Kerr's practice, but I would caution every young gardener against the use of paraffin. In the year 1873 I mixed some with paint which I was preparing for Vines and Peach trees, the former being much infested with mealy bug. I did not perceive any harm it did the Peaches, but my strong hee by Vines were so much affected that the buds as they began to wither, and it was a long time before they anything like recovered. I have never used paraffin since. Peach trees infested with scale can be successfully cleaned of them by washing the trees with soft-soap water during winter, and afterwards dressing them all over with a composition of tough clay, sulphur, and tobacco water.—B. G., *Co. Down*.

NOTES AND GLEANINGS.

IT was announced in the annual report of the ROYAL HORTICULTURAL SOCIETY that the Wednesday Committee meetings will henceforth be held in the conservatory, after which a military band will be in attendance. The next meeting of the Committee will therefore be held in the conservatory, and a fine Show is anticipated.

—WHAT *Azalea amoda* is amongst its species—namely, small, early, and distinct, so is EARLY GEM amongst Rhododendrons. This, as it has been exhibited by Messrs. Veitch, is exceedingly early, dwarf, and floriferous, and for producing pleasing masses of flowers, either in the garden or conservatory, it is a plant not to be overlooked. The colour of the flowers is rosy lilac, and the plant is of very close habit. It must be regarded as an acquisition for winter and spring decorative purposes, its natural precocity rendering but little forcing necessary to assist in unfolding its numerous flowers during the early months of the year.

—"I NEVER before saw so much blossom on the LAURENTIUS as there is this year. All the winter it has been most useful for the flower stands, and with a few green sprays from the shrubbery and a few Primulas to give colour has been very effective, and since the Crocuses, Heath, and other spring flowers have come in still more so. I do not consider it later than in some other seasons—last year for instance. Some blossoms always come out in the autumn, and the others wait for heat, but occasionally the frost in winter is so severe that all the remaining blossom buds are destroyed, and in comparison with those seasons the present blossom may be said to be later, but not otherwise.—AMATEUR, *Cirencester*."

—WE have received the following note from a "City Man" in reference to SUTTON'S GOLDEN GLOBE SAVOY:—"I have had three sorts of Savoys sent me from a garden in Surrey, and could not resist admiring the beautiful appearance of Sutton's Golden Globe. When cooked it was also the most tender and delicate in flavour of the three. Its colour may be an objection with some, but I think no one can dispute its superior quality."

—THE following HARDY HERBACEOUS PLANTS flowered during February at the Messrs. Rollisson & Sons, Tooting Nursery:—*Galanthus plicatus*, *G. nivalis*, *Scilla sub-niva*, *Saxifraga rubra*, *S. oppositifolia major*, *S. oppositifolia pyrenaica*, *S. cordifolia*, *S. Stracheyi*, *Dianthus Maria Perle*, *Eranthis hyemalis*, *Hepatica angulosa*, *H. triloba alba*, *H. triloba staminudis rubra*, *H. triloba rubra*, *H. triloba rosea*, *H. triloba cœrulea*, *Iris reticulata* (fragrant as Violet), *Sisyrinchium grandiflorum*, *Ery-*

thronium dens-canis in variety, Muscari pallidum, Primula denticulata, P. polyantha, Helleborus niger, Aubrietia deltoidea grandiflora, and Tritileia grandiflora.

It is not generally known that anyone may now become a member of the ROYAL HORTICULTURAL SOCIETY on the payment of an annual subscription of one guinea, and this entitles them to free admission to all shows, promenades, and meetings of the Society except the annual meeting. In short, it gives the privileges of a Fellow with the exception of voting at meetings on questions of government and finance, and these are privileges which not one in a hundred of the Fellows ever avail themselves of. What people mostly want are to be allowed to walk in the gardens and to attend shows and promenades, and this they can do by becoming guinea members.

MR. N. HODGKIN writing to us from The Gardens, Downgate, Sandhurst, Kent, on the MILDEWS of the SEASON, states that he has now (February 12th) Veroniceae, Hepaticae, Heaths, white Mezereon, Snowdrops, Crocuses, Jonquils, white and yellow Narcissus, and Hyacinths, all in full bloom. He has gathered Roses all the winter, and on February 13th Gloire de Dijon, Général Jacqueminot, Souvenir de la Malmaison, Maréchal Niel, Lamarque, and Banksian Yellow, as good blossoms as in summer, from north-west and south-east walls. Leaves of bulbs of all kinds are above ground; Lilium punctatum, roseum, album, rubrum, and longiflorum are 9 inches high, all in the open ground. A Daphne indica rubra planted in a sheltered position has been in full bloom for the last six weeks, and vegetation generally is in a very forward state.

In "The British Trade Journal" is a portrait and memoir of Mr. MARTIN HOPE SUTTON, of the well-known Reading Nursery firm. It states: "The day of his nativity (March 14th, 1815) was one of misfortune. On it occurred a bank failure, by which his father was seriously affected, and this calamity was intensified by the news that a large London house to which Mr. Sutton père was in the habit of consigning large quantities of flour had come to the ground. The worthy gentleman seems to have maintained a bold front in the face of these reverses, and to show his confidence in the fulfilment of the motto, 'Le bon temps viendra,' gave to his son the name of Martin Hope. In 1832 the youth was promoted from school to a place in the parental counting house. His father's business, located in Reading, was that of a miller and corn merchant, an offshoot being small dealings in agricultural seeds. Young Sutton was an enthusiastic botanical student, and a lover of floriculture for its own sake, and he was allowed to dabble at his own risk in the raising and selling of garden seeds, a branch which his father deemed too insignificant to form an integral part of the seed business. His sober ambition was to establish a nursery garden, and by-and-by it was realised. A small plot of ground was secured, and it was not very long before a gorgeous Tulip bed in connection with it became in the blooming season one of the local attractions of Reading. In 1837 the quiet enterprise of the young man met its reward in the establishment of partnership relations between himself and father, under the firm of John Sutton & Son. Their nursery began to gain a repute, and at the time when Dahlias were the fashionable rage in horticulture, their floral collection was referred to by Miss Mitford in a charming article entitled 'The Loet Dahlia,' which appeared in 'Chambers's Edinburgh Journal,' as 'the most choice and select I have ever seen.' In the year 1843 Mr. Alfred Sutton, who had for some time been actively associated with the business, was admitted as a partner, and the firm assumed the title of Sutton and Sons, by which it is still known."

As an instance of the mildness of the winter in West-morland there is in the gardens, Fox Ghyll, Ambleside, a SCARLET RHODODENDRON IN FULL BLOOM. The first flowers cut from it were on the 19th December. It is usual for it to flower about Christmas, but as a rule gets cut down with severe weather. The Laurustinus also are two or three weeks earlier in flowering than they are generally.

MR. FITHERS, The Gardens, Munster House, Falham, has sent us sprays of AUCUBA JAPONICA more heavily laden with berries than any that we have hitherto seen. The sprays have been cut from large shrubs which have had no male plants near them, and their fruitfulness can only be accounted for by the distribution of pollen conveyed by the wind from Mr. Dancer's Nursery, about 200 yards distant from Munster House. This is another proof that it is not always necessary to place the male and female plants side by side for ensuring a crop of fruit. We remember having seen large Aucuba bushes at

Denbies covered with fruit without artificial fertilisation having been resorted to. Male plants flowered in the garden some distance from the female shrubs, and the wind conveyed the pollen in the most effective manner. All who possess shrubs of the old mottled Aucuba should also obtain male plants, and the beauty of their shrubs will be enhanced when producing clusters of brilliant scarlet berries.

"N. B." sends us a note saying that if JUSTICIA FLAVICOMA recently mentioned by Mr. Anderson is identical (as he thinks it is) with Schaneria calicotricha he can endorse all that has been said in its favour, as he has found the plant which he has under the name of Schaneria one of the brightest and best of winter-blooming plants.

"MIDLANDER" asks what acid is in the GOOSEBERRY? We print in reply the following analysis made by M. Berard. Green Gooseberries have been analysed by him, both before they were ripe and when ripe:—

	Unripe.	Ripe.
Chlor. phyl. (green coloring matter)	0.65	0.64
Sugar	0.53	0.78
Gum	1.86	0.88
Albumen	1.07	2.41
Malic acid	1.20	0.81
Citric acid	0.12	0.99
Lime	0.84	8.01
Fibrin, including the seeds	86.41	81.10
Water	100.00	100.00

WHOEVER wishes for full and authentic information of all kinds relative to the COLONY OF VICTORIA should refer to the "Notes" published "by authority." It is historical as well as geographical, meteorological and statistical. It records that there are there 1500 gardeners not domestic servants; that about £40,000 worth of Potatoes are exported yearly, and the following prices of some garden products in 1871. Potatoes, wholesale, £4 to £4 10s. per ton; retail, 3d. to 1d. per lb.; Onions, dried, 9s. to 20s. per cwt.; Carrots, 6d. to 1s. per dozen bunches; Turnips, 6d. to 2s. per dozen bunches; Radishes, 4d. to 6d. per dozen bunches; Cabbages, 9d. to 10s. per dozen; Cauliflowers, 2s. 6d. to 8s. per dozen; Lettuces, 2d. to 2s. per dozen; Green Peas, 1½d. to 4d. per lb.

MESSRS. BACKHOUSE & SON state GALANTHUS IMPERAT is the finest of all Snowdrops. The leaves are narrower and altogether smaller than those of G. plicatus (the Crimean Snowdrop), while the flower is larger, the petals being nearly or quite one-half longer than those of G. nivalis. A graceful Snowdrop, resembling the common one, but with flowers nearly 1½ inch long, forms no ordinary addition to our early border plants, and must be welcome everywhere.

We regret to have to announce the DEATH of Mr. HENRY ORMSON, the eminent hothouse builder and hot-water engineer, which occurred on Tuesday, 20th of February, in the Isle of Wight, where he had gone for the benefit of his health.

MR. DARWIN has received as a TESTIMONIAL, on the occasion of his sixty-ninth birthday, an album, a magnificent folio, bound in velvet and silver, containing the photographs of 154 men of science in Germany. The list contains some of the best known and most highly honoured names in Europe. He has likewise received on the same occasion from Holland an album with the photographs of 217 distinguished professors and lovers of science in that country. These gifts are not only highly honourable to Mr. Darwin, but also to the senders as a proof of their generous sympathy with a foreigner; and they further show how widely the great principle of evolution is now accepted by naturalists. A German correspondent informs us that the German album bears on the handsome title-page the inscription "Dem Reformator der Naturgeschichte, Charles Darwin."—(Nature).

AZALEA PESTS.

It is well known that Azaleas are extremely liable to become infested with insects, especially red spider and thrips. The time these are most likely to become established is when the plants are in bloom, as syringing or fumigating cannot be done then. After they go out of flower it is a very general practice to place the plants in a vinery to start them into growth. The insects have then a fine opportunity of making their way on to the Vines, and they are not slow in availing themselves of the chance. Now it is very desirable that this should not take place, because when the insects find their way to the Vines thus early they are certain to do much mischief before the end of the

season; whereas if they were not introduced with the Azaleas it is more than probable they might never have found their way in. My advice to all putting Azaleas into vinerias at this or any other time is to be certain that they are thoroughly clean. I have found no difficulty in killing every insect by the following means:—I fill a large tub or barrel full of clean water. Tobacco juice is then added until the water is the colour of London porter. Gishurst compound is then dissolved and added until the water looks like soapuds. The plants are then in an inverted position submerged in the solution and allowed to remain about one hour, and I have not seen the insect which will survive this treatment. The mouth of the pot is rested on pieces of wood laid across the tub. When they are taken out of the water the mixture is not hurriedly syringed on the leaves, but, on the contrary, it is allowed to dry on, and this I am of opinion gives the leaves a disagreeable taste to the insects for a long time afterwards.—J. M.

ROYAL HORTICULTURAL SOCIETY.

My first letter on guinea fellowships, printed on the 21st of October, 1873, called "upon some one with time and a fresh head at his disposal to come forward and take the lead," and it was only when no one responded that, rather than a good work should be shelved, I determined after urging the Council about this time last year to make the appeal to the country, to attempt the work myself.

I said, and say still, that our successful experiment tried in this neighbourhood is in my opinion absolutely conclusive. If we could get about fifty owners of gardens who had either never joined the Society or who had left it, to express their willingness to become guinea Fellows or find a substitute, it is nearly certain that with time and work other neighbourhoods would do likewise, with the result that we should have Fellows enough to furnish all the funds which could possibly be required.

"A GUINEA MAN" considers that "the results have been impotent." I do not agree with him. In our first issue of names of would-be guinea Fellows there are a greater number of those of the representative horticulturists of the country than are contained in the long last-printed "list of Fellows," that of 1873, before the great defection took place. "A GUINEA MAN" quotes Mr. H. J. Veitch's speech at the meeting of the 13th. I think Mr. Veitch should have given me notice of his change of mind, though this cannot have been a very decided one, as he said publicly after the meeting that he still believed in the guinea fellowships; but he certainly should not have stated that one-third of our would-be Fellows were already Fellows of the Society. Our names were 377; out of these forty-three were, or had been (some had left) "already Fellows," but five of these were life Fellows who had compounded, therefore any further payment from them would have been so much to the good. So, in fact, instead of two-thirds as stated, more than nine-tenths of our names were practically new.

I fully admit that some who, like "A GUINEA MAN," were "invaluable in the guinea scheme," rather disappointed me. (Did "A GUINEA MAN" ask a single friend to join?) But where influential horticulturists took trouble in some districts they brought in excellent names. Witness Col. Page of Llandaff, Rev. Harper Crewe of Tring, Dr. Lionel Beale of London, who all collected first-class names. Miss Hope of Wardle, too, brought in three very good names of ladies, besides her own well-known one. Our number of names are the results of the labour of but a few; with a little more study and experience we shall learn how to induce more to work. Our short list, too, contains such influential names that it must tell. Some first-class names have come in since our list was printed. A Yorkshire horticulturist, with his county's energy, has gone to the expense of a lithographed letter from himself, which he is sending round in his district with our circular enclosed.

Now as to the future. What has made me work is this strong fact, that the Society has never for any time together (since its very early days when it started as a scientific society), prospered. It has never trusted to those most interested in horticulture for its support. All other scientific societies have trusted to those most interested in their several objects and have prospered. I believe if we should so change the constitution of our Society as to resemble theirs in the above respect, horticulture having more friends through the country than any other science has, it would become the most prosperous Society of all.

The Council have admitted three classes, one of Fellows paying £4 4s. and having two transferable tickets, a second paying £2 2s. having one transferable, a third members without a vote having one non-transferable ticket. I believe one reason for withholding a vote from these last was the fear that so many in the neighbourhood might become guinea Fellows that their votes would swamp those of Fellows not on the spot. A member of the Council, after the meeting, I understood to say would have supported guinea fellowships to those living outside the London letters. If the Council would agree to this, I think that many of the best horticulturists of the country rather than wait until 1892 would come in, though some would not. Fellows living out of town have less good from the gardens, therefore it seems fair that they should pay less. It has been said, Let those who want to vote pay £2 2s. Not a few of the very best horticulturists of the country cannot or will not pay more than a guinea, and I do not think it reasonable to ask more from them. Anyone looking at our list will see supporters from distant parts of the kingdom; many of them when sending their names said that they could not expect personal good, but to help a Society for promotion of their favourite science they would become guinea Fellows. I must again remind, that some of the best horticulturists in the country whose names would add strength to any society, and who have great influence in their districts (especially clergymen), are often not overburdened with guineas in proportion to the number of calls upon them, and that a guinea is as much as they will or can be expected to spare.

If these representative horticulturists would come in—and I believe they would in numbers—the Society would be leavened with the horticultural element which has been the great object of our work. Some would say the Society has still the South Kensington encumbrance. True, but if they were asked only for a guinea it is not they who would pay for this, they would get horticultural consideration for their guinea, while the £4 4s. and £2 2s. subscribers would pay for the South Kensington Gardens. These have often been likened to a white elephant, but it is not the white elephant (at least as far as horticulturists are concerned), that is an evil, but the having to pay for its keep, and this they would not have to do. If the Council will not grant guinea fellowships with votes to those living outside the letters, I would counsel going on collecting names and waiting, trusting to the chapter of accidents. The Council may rechange their policy, the £10,000 for the year may not be raised. The public or Parliament may effectually protest against the land bought with the people's shillings being used except for public purposes. In any case, judging from the tone of letters to me, I think the best horticulturists will not, by giving guineas for a membership without a vote, to that extent bolster-up what such a long experience has shown to lead only to unsuccess.

"A GUINEA MAN" speaks of the "approval of silence" of the meeting when guinea members were not given votes, and mentions that I was present. Guinea membership not having been mentioned in the report, I at first thought the Council had let it drop; but any way, the idea of guinea fellowship outside the letters not having then been suggested, and our supporters having only given their names for fellowship with a vote when free from encumbrance, we were not concerned in the matter; besides, I deny that silence gives consent, or means more than a desire to avoid needless discussion. For instance, the report says of the fortnightly meetings—"The large attendance of Fellows and their friends that are usually seen at these meetings." I whispered to my neighbour that I thought that the attendance had been notoriously painfully small, but did not consider it my business to protest against the statement.—GEORGE F. WILSON.

The following letter from Mr. Haughton has appeared in the *Pall Mall Gazette*:—

"SIR,—I do not in the least contest your right to criticise the acts of the Society and of the Commissioners; but I may not unreasonably ask for accuracy in the statement of facts when you seek to condemn the efforts of the Council of the former body on their merits. In your article of yesterday you speak of "public land" which the Society monopolises; its land being in fact no more public than that of St. Bartholomew's Hospital or of one of the City companies. The Commissioners hold in fee their South Kensington property as trustees for certain purposes which our law terms charitable. The benefit of that property by dedicating part of it as an ornamental garden was one of the objects avowed on the face

of the agreement to carry out which the Society's charter was granted; and the event has proved that the South Kensington Gardens have added to the surrounding property much more than their original value plus the money spent on them. The Society has so spent 75,000 on permanent works, and £20,000 or £30,000 on materials and labour—in all something like £100,000, which the advocates of the public now ask to confiscate; and it no more monopolises its gardens than the proprietors of the *Pall Mall Gazette* monopolise that popular journal. Opinions may reasonably differ as to what is a fair rent, but that paid for the gardens by the Society during the last fifteen years has considerably exceeded in amount that paid during the same time by the Royal Botanic Society for an equal acreage in Regent's Park. Your statement that the Society 'could not exist if it depended wholly on South Kensington' may be true if (as in your article) you limit this district to two or three streets, but it is otherwise if you extend it so as to embrace the metropolitan Fellows who enjoy the gardens there. So understood it would be more correct to say Chiswick on its present scale could not exist without South Kensington, for the scientific work carried on at the former place absorbs every penny of what I may be allowed to call purely horticultural subscriptions, together with a considerable rate in aid from the latter. In conclusion, I may say that if you will honour the Society with your presence at the next fruit and floral meeting on the 7th of March, you will not only see a display of plants worthy of the best of its bygone days, but will also be able to satisfy yourself that the gardens are far from being a wilderness."

NOTES ON POMOLOGY IN HEREFORDSHIRE.

(Read at a meeting of the Woolhope Club by the Rev. C. H. Fulmer.)

I WILL in my retrospective survey take a glance at the historic Apples and Pears which were formerly cultivated in Herefordshire, although most of them are best known now-a-days by their varieties. It seems to me I can most practically thus treat my subject, because I thoroughly endorse Andrew Knight's remark, though contrary, I am aware, to the opinion of the best old pomological writers, that "Herefordshire is not so much indebted to its soil as to some valuable varieties;" and in commenting on these varieties seriatim I shall be able to show you further that there is also great truth in another remark of Andrew Knight, that from the description that Parkinson (who wrote in 1629) has given of the Apples cultivated in his time, it is evident that many of those known by the same name are quite different and probably new varieties, some being so altered for better or worse as to assume quite a new seasonal or structural character. Among cider Apples, to which these remarks specially apply, the Redstreak or Scudamore Crab then reigned supreme; the early-fruiting Genet Moyle, its hardly formidable rival except with the ladies—both varieties long years ago overtaken and swept away by the tide of time; the Must and Golden Pippin, pigmy anatomies of their former selves; while the Foxwhelp and Styre in a moribund state are only existing on their past reputation, which their numerous progeny unfortunately does not in any degree give promise of sustaining.

I will take first some of our historic perry Pears on account of their extreme longevity and from being so well known to us all. The Teignton Squash is first in point of excellence if not of antiquity, having existed without doubt at the beginning of the sixteenth century. Its origin is unknown. Although in the last stage of debility and decay the old trees bear well, though disappearing fast. The growth of the Teignton Squash resembles very closely that of the Longland, a variety which is still flourishing, and of all Pears I should call the farmer's friend, as its fruit keeps fairly and makes very good perry; while to the housewife nothing can exceed it as a stewing Pear in richness and colour, before the Catillac and other late stewing Pears come into season. The Oldfield, however, is the best Pear we have, whether its fecundity or the lasting qualities of its fruit or perry is considered. Evelyn mentions in his day (1706) a gentleman who had some bottles of Oldfield perry brought him from a distance of eight hundred miles that was over forty years old, as rich and high-flavoured as ever it was—a perfect regale he calls it. I can also endorse Evelyn's eulogium, "*Penes auctorem fit fides*," as I have tasted some bottled perry from this variety over forty years old in perfect condition made from my own glebe orchard from original trees, I do not hesitate saying, although in full bearing, that are in their third century. These, however, I regret to say, are iso-

lated facts—the exception, not the rule; as the description of Palladius holds good now-a-days as in his time, centuries ago, that perry, chiefly owing to its irrepressible fermentation, "*Hycum durat, sed prima accessit estate*." The most picturesque and popular without doubt is the venerable Barland or Bearland, originally of Bosbury; the same old lofty-growing trees we see growing now most probably filled the tankards of the Herefordshire farmer and his guests in the seventeenth century, and is more a sister beverage—a right sort of smoke-pipe perry, as an old right-sorted farmer himself described Foxwhelp cider—than any other. Of desert sorts of historic Pears time will only allow of my mentioning two—the Easter Beurré and Beurré Diel, and to find them a local and special history. These two varieties, I have ascertained, were shown in far larger quantities at the last pomological exhibition than any others, and both in their selection and production reflected great credit on the growers. Looking at the market price of fruit in Covent Garden a short time back, and before the London season began, I found these two identical Pears alone mentioned by name at what must be considered the highly remunerative price of 5s. to 12s. per dozen; while Elenheim and Ribeton Pippins (again strange to record), shown at our pomological exhibition both by far greater quantities than any other variety of Apples, fetched from 12s. to 18s. per bushel. It is well, I believe, to comment on facts like these when in Herefordshire, the orchard of England, so many tons of first-quality fruit are suffered to perish through want of seasonable pruning, sheltering, or picking, or still more unpardonable neglect of the simplest rules to be observed in subsequent hoarding. Thus the homo counties and Hertfordshire, and even some parts of Yorkshire, who, as Phillips sings—

"do not disdain to learn

How Nature's gifts may be improved by Art,"

command a ready market; while Herefordshire, with the finest natural advantages in the world, is obliged perfunctorily to depend upon the impetuous visits of the huckster for the sale of her immense surplus stock of what she has only to thank herself for being pit fruit and pot fruit.

As I must hurry on, I feel, to bring my paper to a close, I will only give you a list of the most celebrated of the historic varieties of Apples, making a few remarks afterwards chiefly as regards the nomenclature and varieties of those oldest, best known, and valued.

The Joan or Juneating and Margaret, the Pomeroy, the Cat-head and Costard, the Winter Quoining or Queening, the old Pearmain, the Russet or Royal Russet, the Lemon or Quince Pippin, the Golden Pippin, the Nonpareil, the Befging and the Margil; and among cider fruit the Red Dymock, the Forest Styre, the Royal Wilding, the Redstreak, the Woodcock, the Foxwhelp. This list, I believe, includes nearly all that may be styled the historic varieties, some flourishing, some lingering on to the present day.

The etymology of the Joametting or Juneating Apple is so singular and decides the names of so many other Apples and Pears, that I shall not apologise for selecting it. It is one of the oldest and earliest bearing Apples, hence the mistake about its name being Juneating, in allusion to its maturity at the end of June or July. Dr. Hogg traces its name to Joametting, because its Apples ripened about St. John's day; and for a similar reason the next Apple I mention, the Margaret Apple, derives its name from St. Margaret's day, the 20th July, when this Apple would be in season. The Costard is one of the oldest of our English Apples. This variety is actually mentioned by name in a fruiterer's bill in Edward I's reign in 1292, as previously alluded to; and although now almost extinct, still used to be so common that retailers of it (even the very price mentioned at 1s. per 100) were called costard mongers, a name in popular use now in the word costermonger. Some etymologists, including the great Dr. Johnson, consider the name Costard to be derived from *cost*, a head, but how it is hard to say or rather to see. Dr. Hogg traces the name to *costatus*, *anglice* costate or ribbed, on account of the prominent ribs on its sides. The Quoining or Queening Apple is an old Apple, of which we have many varieties in Herefordshire (notably the Cowarne Quoining, a most valuable Apple) which were excellently and numerously shown at our pomological exhibition. The name Quoining may be traced by the angularity of the shape of the Apple, similarly as in the Costard, from the word quoin or coin, the corner-stone of a building. The Cathead is another very old Apple still grown amongst us, but chiefly I have noticed in cottagers' gardens, where it is gradually giving way to the Hawthornden and Lord Sunfield,

especially in Hertfordshire. Phillips sings its praises thus—"The Cathead's weighty orb enormous in its growth." The Old or Winter Pearmain must by no means be omitted. It is the very oldest historic variety we have. In Bloomfield's history of Norfolk, as quoted by Hogg, there is curious mention made of a tenure in that county by petty serjeanty and the payment of two hundred Pearmains and four hogsheds of cider of Pearmains into the Exchequer at the Feast of St. Michael. The origin of the name is equally curious. In early historical works of the same period Charlemagne is written Charlemaine, the last syllable as Pearmaine; and as Charlemagne was derived from Carolus magnus, so Pearmaine is derived from Pyros magnus, the Great Pear Apple, in allusion to its pyriform shape. The Lemon or Quince Pippin is mentioned by Ellis in 1744 as so good an Apple for all ages that many plant this tree in preference to all others. I know a nurseryman in my very neighbourhood who has several trees of this variety in wonderful bearing, but he says he could sell twenty times the quantity he has to different nurseries, where, owing to its brisk and refreshing taste, it is a special favourite.

The Golden Pippin, although of the greatest antiquity, has very little early history. It is not the Golden Pippin of John Parkinson, because he speaks of it as a large variety. Evelyn, in his Pomona, states that Lord Clarendon had in his time at his estate in Berkshire an orchard of a thousand Golden and other cider Pippins, but no allusion is made to it as a dessert Apple. The Margil is still grown successfully in Hertfordshire. It is said to have been originally introduced from Versailles in 1750. This Apple was shown very nicely at our last pomological exhibition. In delicacy of flavour it is unsurpassed, but unfortunately it is a shy bearer, owing chiefly to its blossoms suffering from frost more than any other Apple. The last, although one of the earliest historic Apples, I shall mention is the Pomeroy or King's Apple. This Apple is of extreme antiquity, very little is known of its early history. In Hogg's "Fruit Manual" (a work most judiciously added by Dr. Bull to the Free Library), and from whose descriptions I have largely borrowed, two distinct varieties are mentioned in use nearly at the same time, but differing altogether in shape, flavour, quality, and colour of flesh. I take particular interest in this old and highly valuable variety, because in my parish we have three or more very old trees still flourishing, and I was glad to see this Apple shown from many parts at our late exhibition. The original variety of Pomeroy still bears very fine juicy and delicious fruit in September, but which very soon perish; indeed last year many Apples decayed while hanging on the tree. This undoubtedly would be the Pomeroy of Somerset mentioned by Hogg, though he puts back its season too late from October to December. Now I was shown, indeed I tasted, a fortnight ago a specimen of the second variety, the Pomeroy of Lancashire, which had been bought in the Hereford Christmas market under the pseudonym of the Green Blenheim. This cannot be the true Pomeroy, as this variety does not answer at all to the description given it by the old writers neither seasonably nor structurally. I was pleased to find in Foreyther, who wrote his treatise in 1810, that this is only a late variety of the true Pomeroy. He describes it as the Winter Pomeroy, a good baking Apple and keeping till January. I should say this might be a variety of the true Pomeroy promiscuously crossed with the Nonpareil to one of its many varieties, as it bears strong resemblance to this Apple.

The most interesting of our cider historic Apples which may be considered as existing now are the Dymock Red, the Royal Wilding, the Cowarne Red, the Thyme's Kernel, the Forest Styre, the Underleaf, the Woodcock, and the Foxwelp. Of these varieties I will only briefly say that the Dymock Red is either a different Apple altogether or altered strangely in character. Now it is one of our earliest and best cider fruits in the Ledbury district, while in Forsyth's time a Dymock Red similar otherwise in description kept from January to March.

The Royal Wilding also demands a special notice. It is one of our best cider fruit, and I always thought that Hertfordshire had the credit of raising it until unobserved by Dr. Hogg, who claims that honour for Devonshire. Now, I find in old Barry Langley so different a plate altogether of the Royal Wilding in his time to what it is now with us, that I must consider them two distinct varieties of Apples until disproved by seeing a specimen of this fruit in the autumn from Devonshire.

The Woodcock is extensively grown in several parts of

Hertfordshire. The trees that I have seen are generally pictures of healthiness and fecundity, while the fruit bears the undoubted characteristics of the original species in structure, especially as regards a curious enlargement on the side of the fruitlets. Still the cider now-a-days is miserably poor—thin and whelp-like, and not at all in keeping with the high reputation it held among writers in the seventeenth century.

Of the Forest Styre I have failed in obtaining any history whatever. It is mentioned by the oldest writers, and its praise extolled to the skies when grown on light and chalky soils. It is an early sort, and the strength of its cider immense. I am told grafts from the old trees canker soon and perish sooner or later; while the cider made now is harsh and has lost all that charm of flavour for which formerly it was so celebrated.

With the Foxwelp this is not the case, I mean with the original trees. If fruit only can be had the flavour or gust is most pronounced; but from any other trees than the original this flavour is barely perceptible. With this piece of information I come to a full stop. Evelyn dismisses the Foxwelp in a single line contemptuously "as making a cider that requires two or three years to come round." Can I with any sense of self-respect or in common justice believe to the last and dismiss hurriedly our prince of Apples, the sole survivor in the race of time—our highly-flavoured fruit, that like Shelley's flower is dying of its own sweet loveliness, and like the expiring swan is singing only in its death? No, we orchard lords of Hertfordshire, as represented by the Woolhope Club, mean to pay the highest tribute in our power, and to make its fame immortal by allotting to the Foxwelp Apple the pride of place in the first number of our standard Hertfordshire Pomona; while as to myself I will not, I repeat, insult a time-honoured lichen-shedded giant by giving him now a beggarly passing notice; but thanking the company for their attention, will leave to some brother member the high privilege of reading a special paper in honour of the Foxwelp, on its longevity, its specific untransferableness, and its unrivalled power in the words of Evelyn speaking of all good cider, "in soberly exhilarating the spirits of us hypocondriacal islanders."

WOOLLY APHIS AND THE AURICULA.

I OBLIEVE to say that I must be added to the list of sufferers by this pest, the existence of which, as far as the Auricula is concerned, I was utterly ignorant of until the letters that have lately appeared in the Journal attracted my notice. I had been much disappointed with the appearance of some of my plants after top-dressing. They did not move with accustomed vigour, and as the loam which I used had been laid up for some years I concluded it was at fault, but against this was the fact that some of the plants were as fine as usual. When the letter of "A. S." appeared in last week's Journal I thought me, Can I have this plague? and so in fear and trembling I went to my frames. The first plant I examined was one of C. J. Perry. I turned it out carefully, and alas! all along the roots which had well filled the pot were the white woolly threads, which I am afraid must be it; if so, my failure is to be accounted for. I know not what to do. To turn them out of their pots now would be, I fear, hurtful, and would spoil all my chance of a bloom (now I fear but a poor one), and yet if I leave them alone I am afraid of the effect on the plants. Need it be said that I feel this to be a great calamity? We are about to have a grand tournament in London, and, although the owners of "the large battalions" in the north are coming with force, I should like to have been in the *melée*, and still hope to be in a small way; but this will very materially hamper me. I am in a difficulty here for shade, and during the summer place my frames under a hedge near which are some old Apple trees, and I fear it is from them I must have the pest. These insect ravagers are most mysterious. I have grown Auriculas for forty years on and off, and yet I never heard of such an enemy as this before. It is not alluded to in any writings on the flower that I am acquainted with, and all at once we hear of it in various directions; and the beasts cannot certainly have communicated one with another, and said, "We have had enough Apple diet for some time, suppose we go in for Auriculas." We unfortunate sufferers are indeed to be pitied.

While writing of garden pests will you allow me to say that the trustful gentleman who said that red-leading Peas was a complete protection against mice is a gay deceiver? at least the Kentish mice are above being stopped by such mean devices. My first sowing of Emerald Gem was well red-loaded, but not.

witstanding this not only have the mice been at them, but I found some of the Peas still retaining the red on them carefully laid up in a corner of my Auricula pit, ready for another meal. I must now try paraffin. Is it to be used pure or diluted?—D., Deal.

THE ANCHOR-FOOT STANDARD FOR WIRE FENCING.

Wire fencing is an article which is so much used in the partition of parks, pastures, and moors, that the mode of fixing it is of the greatest importance. Next to strength, the mode of fixing it in the ground is the consideration most to be attended to. We some time ago had brought to our notice a standard manufactured by Messrs. A. & J. Main & Co., of Queen Victoria Street, E.C., which we have found by experience to be very effective. It is represented in the accompanying engraving, and it is distinguished by the name of the

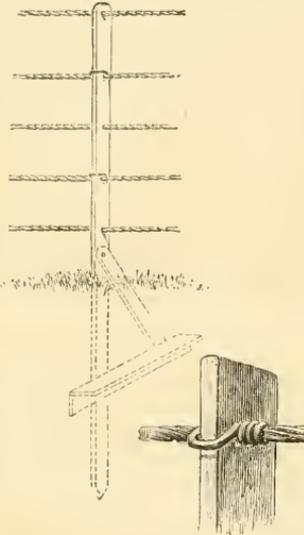

Fig. 21.

"Anchor-foot standard." We have used it rather extensively for separating pastures and as boundaries of farm roads where there are no live fences, and we feel ourselves justified in speaking of it in the highest terms. Its power of resistance to cattle is perfect. In our own case the standards are 9 feet apart with six and seven lines of galvanised wire, and this we have found so strong as to resist the charge of a young horse, which when first turned out rushed up against it, ignorant of its existence. Notwithstanding the force directed against it, not more than two of the standards were displaced, and that not more than 6 or 7 inches out of the perpendicular. With such a test as this it is with confidence that we recommend the anchor-foot standard for wire fencing.

TEA ROSES.

My experience in growing Tea Roses is somewhat different from that of "A YORKSHIREMAN" on page 81. I find that here, a few miles on the west side of Lincoln, on a light dry soil, I cannot by "A YORKSHIREMAN'S" method keep my Tea Roses through an average winter. I always take them up at the latter end of October and lay them in under a south wall, putting a little dry fern amongst them if the weather becomes very severe. I take care, however, to remove the fern or any other protection as soon as there is a change of weather, as I believe the want of a free circulation of air among the branches for any length of time is almost as destructive as the frost.

As soon as I have taken up the Roses I dig a quantity of

good pig manure into the ground (an east border), and dig it over again a week or two before I replant in the beginning of March, and I take care, as soon as I can, to mulch the newly planted Roses with grass cut from the lawn. I lose very few, and in due season am richly rewarded for all the pains I take. I have only half-standards at present, though I have laid-in a stock of seedling Briars, from which I am hoping great things if I can only manage to work them. As I have no glass, and cannot raise any Tea from cuttings, would that "WILD SAVAGE" or any other of your correspondents show me how?—J. E. D.

I THANK the Rev. J. B. M. Camm for his practical and genial notes on Tea Roses, also for the complimentary way he speaks of Leek and its rosarians. They are truly enthusiastic and deserve the praise bestowed by Mr. Camm, and I am sure his advice will encourage us in the attempt to cultivate these beautiful flowers, and I hope we shall be able to report favourably next autumn of our success. I wish they were like that hardy free-flowering Gloire de Dijon, for at Pickwood Hall, the residence of William Challoner, Esq., not a mile out of Leek, were cut on the 13th of January eight perfect blooms of that Rose, and there are several fine fresh-looking buds, which if the weather continues open will be flowers shortly. Will any of your correspondents kindly say if they have seen anything so unusual in the month of January? I ought to say that Pickwood is belted by well-grown forest trees and shrubberies except to the south-west, which looks down a delightful valley—exceptionally favourable. I might also mention that the Clematis is in bloom, and not more than five weeks ago I saw Mr. Challoner with a flower of Rhododendron, which he had cut from a plant the men were removing.—S. EYRE.

OUR BORDER FLOWERS—EVENING PRIMROSES.

If the old saying, "that there is nothing new under the sun," does not apply to anything particular it must be to flowers, for they are ever new, and the more we see of their beauties and inhale their fragrance the more we enjoy them. *Oenothera biennis* is now so well naturalised in some parts of the country that only a pinch of seed requires sowing in our borders when the plants come up, and by simply leaving them alone we soon have Evening Primroses in abundance. The *Oenotheras* are an extensive family of border flowers, and were much prized in years gone by when bedding plants were not so numerous as they are now. We used to tend *Oenothera Drummondii* with care and employ it with good effect. The Dandelion-leaved *Oenothera taraxifolia*, with its monstrous white flowers, when pegged-down is a fine plant in the borders; but perhaps *Oenothera macrocarpa* has the largest flowers of the whole family. Many others, as *O. Fraserii*, *O. speciosa*, *O. glauca*, and *O. hybrida*, are all fine border flowers, many of them emitting a delicate perfume. The herbaceous kinds are increased by cuttings in the autumn and division in the spring. They like a moderately dry sandy soil and full exposure. Some one has said that *Oenothera biennis* expands its flowers just as the sun sinks below the horizon.—VERITAS.

THE ROYAL HORTICULTURAL SOCIETY'S GARDENS, KENSINGTON.

THESE gardens occupy about twenty-three acres. They are a parallelogram in shape, surrounded by colonnades and covered arcades, and on the north side, in the centre of the arcades, is a very large conservatory. The gardens are laid out in the Italian style, planned with good taste, and eminently adapted for promenade by numerous intersections of grass and gravel walks, highly embellished fountains, basins, cascades, balustrades, vases of rich design, statues in marble and bronze, and numerous other embellishments; terraces, flights of steps, sloeves, and parapets; sloping lawns, and a variety of surfaces producing pleasing effects. The water for the fountains, cascades, &c., is supplied by an artesian well 400 feet in depth, and is capable of supplying a million gallons in twenty-four hours of a pure and soft quality suitable for the purpose of the garden. The artificial adornments are brought into harmony with the natural beauties of the trees and shrubs, and the various climbing plants twine round and between the balustrades, clustering on the tops and varying the height of the terrace walls in various styles. The arcades, sloeves, and projections from buildings are made supporters of climbing plants, softening down the sharp outlines of masonry.

The trees have grown to a size producing depth of greenness and breadth of shadow, and break the continuity of view, so that the eye cannot range over the whole space as formerly without being attracted to some pleasing forms of vegetation, and in all parts of the grounds there begins to appear that boldness of relief which only time could give. All the decorations of this garden are highly ornamental, and accord with the surrounding style and character of the buildings; and if well kept up it would become very popular, for it is well situated for fashionable resort and surrounded by residences of families moving in the highest society, and the garden preserves an open space in a district which has been fast closed-in by buildings in this fashionable quarter of the metropolis. A garden thus situated could not be better calculated for exhibiting good examples of the high art of horticulture.

All should again unite in fellowship to support the old institution that has done so much good service in its pro-

At this time (about 1818) the Society began the system of procuring seeds and plants from abroad, and distributing them to the Fellows. Plants were first sent from China by Mr. John Reeves, a zealous horticulturist, and by-and-by the Council began to send out collectors on their own account. The assets of the Society increased. The house in Regent Street, which for forty years afterwards was the focus of horticulture in Europe, was bought at the price of £4200. The subscription to the Society was raised from £2 2s. to £3 3s., and the admission fee from £3 3s. to £5 5s.; and in 1821 there were as many as 328 elections in one year.

Stimulated (some have said intoxicated) by this prosperity, the Society resolved to take a lease from the Duke of Devonshire of the present grounds at Chiswick, and abandoning the gardens at Kensington and Ealing, to concentrate all their operations there. The land consisted of thirty-three acres, and was leased at a yearly rent of £300 a-year, with a power

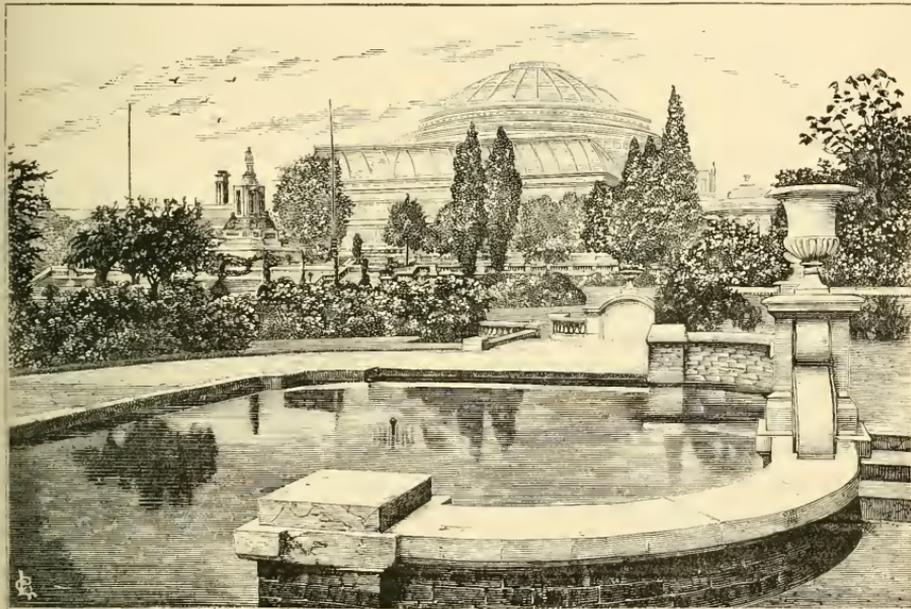

Fig. 23.—ROYAL HORTICULTURAL SOCIETY'S GARDEN, KENSINGTON.

gress of sixty-eight years, fostering and encouraging every branch of horticulture, the articles of necessity rendering the vegetable kingdom still more useful and more pleasurable. Certainly the Society has before been in cloudy circumstances and on the point of extinction, but then the good Prince Consort revived it; his influence restored its prestige, his plans which recruited its funds, and so enabled the Society to construct the garden and restore all to prosperity. Captain Fowke, Mr. Smirke, and Mr. Nesfield furnished plans for the garden, but it was the Prince who first suggested the ideas which they put on paper; it was he who examined the plans, altered, and corrected them until they gradually assumed their present form.

In 1818 it was thought the Society was in a position to warrant the establishment of an experimental garden. The income was £1791; the funded property £1400, and floating property estimated to be worth £3000 (a large proportion of which was, doubtless, arrears of subscriptions). An experimental garden was accordingly established at Kensington, with an auxiliary nursery at Ealing. The turn of events has again brought round a recurrence of the same conditions which existed fifty years ago. The Horticultural Society has returned to Kensington, near the spot where the old garden stood, and it has again its auxiliary nursery, only it is at Chiswick instead of Ealing.

of renewal for ever upon a fine of £450 every thirty years. At the end of the first thirty years this power was not exercised, and a renewed lease at the same rent was entered upon for another thirty years, with power to relinquish possession on giving one year's notice. This lease will come to a termination on the 29th of September, 1881.—N. COLE, Kensington.

KITCHEN GARDENING.

At the usual fortnightly meeting of the Darlington Gardeners' Institute the following practical and useful paper was read by Mr. MacIndoe of Hutton Hall:—

At the present time the want of a knowledge of the culinary garden is undoubtedly an ugly fact in connection with the rising generation of gardeners. This no doubt arises from one of two causes—either from want of opportunity or a disinclination on the part of young men to undergo the laborious drudgery of cultivating the soil. Journeymen gardeners who can very creditably stake a Heath, turn a large Azalea bush into a shapely pyramid, or neatly train a Peach tree to the wires, are frequently met with; but, whilst these things are all very desirable in their way, how seldom do you find a young gardener who can make an Onion bed in a workmanlike manner, and I hold that no man has a right to call himself a gardener until he is capable of making a neat and trim Onion

bed. Again, how rarely do we meet with a young gardener having any knowledge of the different varieties of either hardy fruits or vegetables; and I ask, How many are there who can name at eight say half a dozen sorts of Gooseberries or Strawberries? How many could at eight name three varieties of Peas or of Broccoli? This is, I think, a state of things which we all ought to try and remedy without further delay, as I can conceive nothing so humiliating to a head gardener as his being obliged to acquire a knowledge of kitchen gardening from those under him; and what can lower him so much in the estimation of his men as an inability to show them how to properly handle the spade or rake, arts which cannot well be learnt in after life? I would sincerely urge those who have not had the good fortune to be well trained in the kitchen garden during their apprenticeship to lose no time in placing themselves under some good practical gardener where kitchen gardening is well done, even if this step should involve pecuniary loss and a sacrifice of personal comfort. When a gardener enters upon his first responsible situation he should make it one of his first duties to take stock of the kitchen garden, and, having ascertained as soon as possible the requirements, likes, and dislikes of the family, he should arrange his crops for the following season, allotting as nearly as he can to each vegetable the proportion likely to be at his disposal, and taking care to avoid a glut or a famine at any time.

The following is the plan I adopt:—On some fine day in autumn I go round pocket-book in hand, and on one page I draw a rough plan of the garden, on which I affix a number to each border and quarter; I then number the succeeding pages to correspond, and proceed to allot the next year's crops to each plot, arranging what is to be dug or trenched, heavily or lightly manured. The south borders I consider most valuable, inasmuch as the earliest vegetables are always most highly appreciated, for which reason these borders should always be divided into several parts, of which the first would be occupied with early Peas sown about the second week in November, and which I consider a good crop to precede Strawberries for the following year. Allow me to remark in passing that notwithstanding all the high trumpet soundings about Alpha, Ringleader, Emerald Gem, Blue Peter, or William I., I have not found one Pea to surpass the old Dillistone's Early for the first dish. The adjoining piece of ground I give to early Potatoes, always taking care to have them well sprouted before planting; and for the first dish I have not yet met with any to beat the old Ashleaf Kidney, of which, however, there are many spurious stocks or so-called improved Ashleaf Kidneys. The true sort is easily known, as, when commencing their growth, they have smooth yellow sprouts with green points, whilst the bulk of the others have purple sprouts. In the remaining portions of the south borders places should be found for winter Onions, early Carrots, Turnips, Cauliflowers, Broad and Kidney Beans, Radishes, Lettuce, &c., and when these come off the land is usually in good condition for late crops of French Beans, Spinach, Turnips, Saladings, &c.

The east and west borders are always useful for a variety of crops unseasonal to those grown under more favourable circumstances, whilst the north border is valuable for late Strawberries, Turnips, Saladings, Parsley, Herbs, and many other things. I may remark that it is better not to occupy fruit-tree borders with tall vegetables or anything likely to injure the trees on the walls.

Turning now to the main portion of the garden, we shall have to determine how the quarters are to be cropped. In the first place, a good space must be set apart for Potatoes; and in my experience I have always found that, in addition to manure, Potatoes are much benefited by a little fresh lime being applied to the land at planting time, as, besides the good done to the land, the quality of the Potatoes is much improved. If the land has been recently trenched, and is in good condition after the second early Potatoes, fine crops of late Broccoli, Savoys, or winter greens may be had, and these in turn may be advantageously succeeded by Celery. The year following the main crop of Peas will do very well where the Celery has been, taking care to have the Peas where the Celery trenches were, as in this way the manure serves for two crops. The part of the garden allotted to Carrots, Beet, Par-nips, and Onions ought always to be trenched at least two spits deep some time during the preceding autumn, and well manured for the crop of Onions. The best time to sow spring Onions is so soon as you can trample on the ground without the soil sticking to your boots. I have for a number of years found wood ashes very beneficial to Onions, Carrots, Beet, and Turnips. When

the seed is sown I have the drills filled up with the ashes, the back of the rake is then drawn over the whole, and in due time the seed sprouts strongly through the loose surface, which never cakes, no matter how many showers there may have been in the interim, and, moreover, I never knew Onions, when treated as I have described, to be badly attacked with the grub so common in old gardens. Onions make a very good crop to precede Cabbages, as they are got off the ground early in the autumn, and the Cabbage plants get a good hold of the soil before winter sets in.

You will observe I have not said anything about such vegetables as Asparagus, Globe Artichokes, Seakale, or Rhubarb, which are so often found in back out-of-the-way places; these I consider most valuable vegetables, and they will well repay any extra labour bestowed upon them. Before making a new plantation of these be sure to have the land well manured and deeply trenched, and, with ordinary attention afterwards, success is almost certain. Such are a few general observations on the management of the culinary garden; and in conclusion I would beg to be allowed earnestly to impress on all young head gardeners to look well after the rotation of crops; to keep the garden clean and tidy; to strive at all times to have a variety of vegetables ready for the pot, and not to allow the salad-bowl to be neglected.—(Darlington and Stockton Times.)

DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

HARDY FRUIT GARDEN.

So far the birds have not done any harm to the buds of the Gooseberry bushes, which are now at that stage when they usually attack them. The weather has been mild, and probably green food of another sort has been plentiful. Pruning should now be finished without any delay. We generally leave Morello Cherry trees until the last, but they are now pruned and nailed. The buds on the north walls are starting. It may not be generally known that the Morello as a pyramid succeeds well on the dwarfing (Cerasus Mahaleb) stock, and it is possible to obtain fruit for preserving purposes, as it is not so much relished by the birds as the other varieties. The old Kentish exceeds quite as well on this stock, and they both make wonderfully vigorous growth. The trees have a tendency to become overcrowded with young wood, but this can be avoided by attention in summer, and if it was not thinned-out at that time it ought to be done at once. We have finished forking over the surface of all the fruit-tree borders. Many gardeners object to this operation; they believe that it is unnecessary if not positively injurious. In our light soil it is useful to give an annual dressing of manure, and if this is left on the surface the birds scratch it on to the walks, and the garden never looks in good order; whereas if the surface is merely forked over and care taken not to injure the roots with the fork, the borders look much neater. Should any weeds appear it is very easy to run the Dutch hoe through amongst the trees.

Gooseberry bushes require a good dressing of rich manure. It is not easy to overfeed them; and if the trees were infested last season with the Gooseberry caterpillar it will be as well to pare off the soil under the bushes with a spade to the depth of 3 inches, and trench it down 9 inches or a foot under the surface, bringing up the fresh soil to work under the bushes in the place of that which has been removed. The Lancashire growers plant their bushes on very highly manured soil, and they also give copious supplies of manure water, and by judicious shading and thinning of the fruit they get the benefit of such a size as has not been equalled in any other part of the British Empire.

When it is intended to regraft any of the Apple or Pear trees they ought to be headed-down in the early part of the winter; but if they were not done at that time they may be done at once, and grafting may be performed about the end of March.

The Strawberry quarters have again been hoed over. We are particular to have the plants quite free from weeds at this season and until the flowers open. If the heds are clean at that time there will be no danger of their being overgrown with weeds until the fruit has been cleared off.

CUCUMBER AND MELON HOUSES.

Those who grow the above in frames will now require to pay considerable attention to them. It will be necessary to cover the frames with mats every night, and should there be any symptoms of severe frost they ought to be doubled-matted. At the same time light and air must be as freely admitted to the frames as the state of the weather will permit. When the heat declines it must be increased by linings of stable manure and leaves. The plants will make but little progress in such a weather, and with the cold winds we have had recently it has scarcely been possible to give air. Where there are efficiently heated houses Melons that were sown the first week in the new year ought to be considerably advanced. It is not well to retain the

plants too long in pots, but at this season they ought to be fairly well established before planting them out. The best soil for Melons is good clayey loam, added to one-sixth part of decayed stable manure, and this ought to be trodden into the bed moderately firm.

We have planted out the Cucumber plants raised from seeds early in the year; they require rather more manure in the soil than Melons, and the temperature of the house ought to be 70° at night; while 65° is a more healthy state of the atmosphere for Melons. With the temperature of 70° a considerable amount of atmospheric moisture is necessary; but we have found that this may be overdone. In our house there are two evaporating troughs cast on the 4-inch pipes, and these two would throw off six gallons of water in a twenty-four hours. This was too much, as the plants never continued long in health, when both troughs were kept full of water. When only one trough is used the health of the plants is quite satisfactory. In an early Mascat house it was found that a large quantity of water evaporated from troughs over the pipes was injurious.

PEACH HOUSES.

The trees in the late houses will now be in flower, and with a night temperature of from 45° to 50° the fruit will set very freely. The trees may be gently shaken twice a day to disperse the pollen. In the early houses disbudbing ought to be attended to in time, as the trees are certain to suffer when too much growth is removed at one time. The fruit may also be thinned out in its early stages, allowing a small proportion to remain until stoning commences. It is needless to reiterate instructions about allowing only sufficient young wood to remain for next season's crop; this and instructions as to watering and destroying insect pests may be found in recent numbers.

GREENHOUSE AND CONSERVATORY.

During rough weather the owners of large gardens ought to find much enjoyment in their houses at this season, and a very small forcing house, with the aid of those flowers that are in naturally, will serve to keep a good-sized house gay all through the season. Camellias are adapted for the largest conservatory or for the greenhouse of the humble amateur, and they need no forcing. Cinerarias and Cyclamens supply cut flowers in abundance from Christmas until April or later with only sufficient heat to keep the frost from them. A few pots of Mignonette may be grown in any cold pits or frames, and be removed to the greenhouse when the flowers commence opening. The plants should have a sunny position, and be as close to the glass as possible.

Cuttings of tree Carnations have been put in in a house where the temperature is about 55° at night, and with a bottom heat of 85° they soon emit roots. It is not necessary so early in the year to shade them from the sun, but some loose squares of glass laid over them cause the moisture to be retained about the cuttings. The glass may rest upon the tops of the labels, or in some other convenient way. In selecting cuttings we avoid the large pithy growths, and select only the small side shoots. They strike well in a compost of equal parts of loam, leaf soil, and sand. When the cuttings are rooted the pots ought to be taken out of the bottom heat, and be removed to a cooler place, putting off the plants about two weeks after.

A number of small specimens of hardwooded greenhouse plants, comprising Cape Heaths, Epacris, Gemetyllia, Aphelxia, Boronia, Phacocoma prolifera, and other plants of this description that were repotted in August last year have now filled their pots with roots, and will be repotted at once. Heaths and Epacris succeed best in good turfy peat, with a little silver sand added if necessary. Most other Cape and New Holland plants are the better with a little turfy loam added to the peat. We are careful to use clean pots and to drain them well, placing some of the most fibrous portion of the peat over the pot-sheds. Potting ought to be done in a careful manner. It is no use trying to do such work in a hurry. Many of the specimens will have roots that are thoroughly matted round the ball; with a pointed stick these should be disentangled, and spaces left between the ball and sides of the pot wide enough to allow the fingers to be thrust down; a rammer made of deal ought also to be at hand, as the compost ought to be pressed down rather firmly. Each plant should also be rather moist at the roots before potting it, and must not be watered at the roots for four or six days after repotting. All such plants require plenty of ventilation, but it will be better to keep the house rather close, and shelter from cutting winds until fresh roots are formed. They will very soon lay hold of the fresh material.

We have propagated all the Chrysanthemums that we require, and shall be glad to wheel all the old stools out to the rubbish heap. Plants intended for specimens have been potted into 4-inch, and when these are well filled with roots the plants will be transferred to 7-inch pots. Chrysanthemums are hardy, easily grown plants, but to have them in perfection they must be potted in rich material. The plants must not become root-bound before they are shifted into the flowering pots. There are always a number of cuttings that fail to do well, and it is not safe to turn out the old stools before all the cuttings have started into healthy growth.

Cuttings of Phloxes were also put in; one cutting in the centre of a small pot. They soon strike roots, and when well established they are potted in 5 and 6-inch pots in rich loam, and are very useful for furnishing the greenhouse during August and September.—J. DOUGLAS.

TRADE CATALOGUES RECEIVED.

Robert Parker, Exotic Nursery, Tooting.—*Catalogue of Hardy Alpine, Herbaceous, and Aquatic Plants, Fruit Trees, &c.*

Walter Ford, Farmer, Basingstoke.—*Catalogue of English and American Seed Potatoes, and General List of Garden and Farm Seeds.*

H. Cannell, Swanley Nurseries, Kent.—*Illustrated Floral Guide and General Catalogue of Plants and Seeds.*

Abbott Brothers, Fairlaw, Southall, London.—*Catalogue of Hives and Bee Furniture.*

W. B. Rowe, 65, Broad Street, Worcester.—*General Seed Catalogue.*

William Parham, 280, Oxford Street, London.—*Trade List of Glass Structures.*

William Gibbins & Son, Oldfield Nursery, Altricham, Cheshire.—*General Catalogue of Plants and Seeds.*

Bruning & Co., No. 3, Beak Street, Great Yarmouth.—*Illustrated Descriptive Catalogue of Seeds, &c.*

Webb & Sons, Worsley, Stourbridge.—*Catalogue of Farm Seeds.*

James Backhouse & Son, York.—*Catalogue of Alpine Plants and Hardy Perennials.*

Ewing & Co., Royal Norfolk Nurseries, Eaton, Norwich.—*List of New English and French Roses.*

George Yates, 29, Little Underbank, Stockport.—*Descriptive Catalogue of Choice Vegetable and Flower Seeds, Gladioli, &c.*

TO CORRESPONDENTS.

* * * All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, so doing so subjects them to unjustifiable trouble and expense.

ROYAL HORTICULTURAL SOCIETY'S GUINEA FELLOWS (C. J.).—For a subscription of one guinea to the Royal Horticultural Society you can become a member and have the privileges of a Fellow of attending a meetings and shows of the Society. The only privilege you cannot enjoy is that of voting at public meetings, as you live in the country it is one which you probably care very little about.

VIOLETS IN FRAMES LIGHTED (M. H.).—We think the leaves are infested with aphid, for which fumigate with tobacco; or they may be attacked by mildew, which may be destroyed by flowers of sulphur, applying through a muslin bag to the under as well as upper surfaces of the leaves. Never have we known Violets do so well in frames as this winter. They are planted out, but your are in pots, which may account for the difference. Clear is not nearly so good as Victoria Regina; for one flower of Clear we have half a dozen in a similar space of Victoria Regina, and these larger and better formed.

SEEDLING ROSES (Peachfield).—Take the "bops" and break them to pieces with the fingers, and sow the seeds at once in pots well drained and filled to within an inch of the rim with a compost of turfy loam and one-third leaf soil or well-decayed manure. Having made the soil rather firm and levelled the surface, scatter the seeds evenly and cover half an inch deep with fine soil. The pots must then be plunged to the rim in an open warm situation, and watered with them in dry weather. In April they may be young plants may appear, though not infrequently the seedlings do not appear until a year after sowing. When three or four leaves (not calculating the seed leaves) have formed gently raise the seedlings with a long narrow-bladed knife, and then put in 3-inch pots and place in a cold frame, shading and keeping rather close for a few days. When established in the pots, as they will be in about a month, plant them out a foot apart in rich soil in an open situation. They will grow freely; some of them by the end of August or early September will have made shoots long enough for budding. Two or three stocks may be budded with each. Those which make strong shoots in the following year and flower the season following, but which do not branch, or very slightly. Any not having shoots strong enough to take buds from should be cut down to two eyes, and they will give shoots from which buds may be taken next year. Many would flower on their own roots in the third year, but the best varieties are rather shy bloomers on their own roots.

SEEDLING BRIARS (Idem).—Take up the plants (which appear this spring) in a hot bed, pricking off the seedlings in pans or boxes when large enough to handle, returning to the hotbed or to gentle heat, though they will do in a cold frame if it be kept close and shaded from sun, but gentle heat is preferable, removing the plants to a cold frame after becoming well established, hardening-off before planting out in May. Perilla may be sown early in April in a cold frame or slight hotbed. Perillae at the same time in gentle heat. The Perilla to be pricked off when the second leaves appear,

PLANTS FROM SEED FOR BREDDING (W. H. H.).—Calcocolaria for bedding, if you mean shrubby kinds, should have been sown in early August; but the herbaceous varieties may be sown now in gentle heat, and will flower in August, but they are not good "bedding plants." Lobelia, Petunias, Ageratum, Pentstemons, Pyrethrum, and Cerastium sown early in March in a hot bed, pricking off the seedlings in pans or boxes when large enough to handle, returning to the hotbed or to gentle heat, though they will do in a cold frame if it be kept close and shaded from sun, but gentle heat is preferable, removing the plants to a cold frame after becoming well established, hardening-off before planting out in May. Perilla may be sown early in April in a cold frame or slight hotbed. Perillae at the same time in gentle heat. The Perilla to be pricked off when the second leaves appear,

past years? It can be only done by all true fanciers working together. Secretaries, exhibitors, judges, pen proprietors, committees—all should enrol themselves members of one body and guarantee, come what may, as a body, to oppose malpractices. When such a company is formed and a protest has to be made, or something to be exposed, the name of no one individual must be given to expose him or her to the merciless attacks of the foe, but it must be done in the name of all and carried out by all. Once this is done and fairly started troubles would so diminish, and disqualifications would become so few, that the society would merely have to look out against their renewal, for in the face of a mighty party of all the loyal fanciers of Great Britain the opposing party would be crushed. A dozen names of gentlemen have been mentioned to carry out such a scheme. We give their names here in alphabetical order: Messrs. Atkins, Bissell, T. G. and W. A. Burnell, Cresswell, Dutton, Lingwood, Manby, Matthew, Pritchard, Tindler, and Wood. Among them are brothers of Polanda, Cochins, Dorkings, Game, Brahmas, and French, in fact all of our chief breeds. We ask fanciers who have the interests of the poultry world in their hearts to come forward and make these twelve gentlemen a committee. They were originally selected at random from a catalogue, and are members of no clique or party, consequently they are in every way suitable for the purpose. We repeat, let them be the committee and organise a meeting, arrange for the balloting of members, leaving out all they deem ineligible for any good reason, and let them try to take the matter into their own hands. They are gentlemen of the first fame, and no one can object to join their army under them as generals. Editors and proprietors of journals and managers of exhibitions cannot themselves do these things for the world is ever ready to ascribe to them, private or selfish motives; but exhibitors can themselves do it, and we hope to see it done. What is to be the peculiar badge or mark of membership we will not pretend to propose, but we do say the entrance fee should be small, for the expenses could not be great and all should be enrolled—everyone who has an interest in the cultivation of our feathered friends, from those with the income of thousands to the recipient of a few shillings a-week.

We would especially recommend the committees of shows to belong, even if they are holding only honorary positions and are not themselves fanciers, for they would be able to afford opportunities of checking by discovery nefarious practices, and give aid to the members and in prosecuting inquiries at their shows. In the face of the world is ever ready to ascribe to them, private or selfish motives; but exhibitors can themselves do it, and we hope to see it done. What is to be the peculiar badge or mark of membership we will not pretend to propose, but we do say the entrance fee should be small, for the expenses could not be great and all should be enrolled—everyone who has an interest in the cultivation of our feathered friends, from those with the income of thousands to the recipient of a few shillings a-week.

We would especially recommend the committees of shows to belong, even if they are holding only honorary positions and are not themselves fanciers, for they would be able to afford opportunities of checking by discovery nefarious practices, and give aid to the members and in prosecuting inquiries at their shows. In the face of the world is ever ready to ascribe to them, private or selfish motives; but exhibitors can themselves do it, and we hope to see it done. What is to be the peculiar badge or mark of membership we will not pretend to propose, but we do say the entrance fee should be small, for the expenses could not be great and all should be enrolled—everyone who has an interest in the cultivation of our feathered friends, from those with the income of thousands to the recipient of a few shillings a-week.

Mr. Wallace Smith has done us a great good by getting all fanciers who were in favour of the judges' names being announced in the schedules to send him their names on a postcard; he then arranged them in order and published them, and the benefit has already begun to show good fruit. We should think some such arrangement could be done in this case. All in favour of some such association as has been proposed could send in their names and addresses on postcards to any one of the twelve named gentlemen if they will only hold office; and they can after a certain date, which can be determined upon, also arrange the names and publish them. And that all might know what they were sending in their signatures for we should suggest something like the following:—"The undersigned are in favour of all loyal fanciers forming themselves into an association for the purpose of exposing, and consequently suppressing, frauds at poultry exhibitions." Those then giving in their names could be balloted for by the committee, and so the matter would gradually be worked into shape. As we, however, said before, the larger the number that join the more hope is there for real and permanent success; and consequently we ask all those who have the interest of their hobby at heart to talk this matter over very seriously and see if they cannot come to some determination to arrange the matter to the satisfaction of all, and to the exclusion of no genuine fancier whether it be of poultry or of Pigeons.—W.

THE FORMER BOURNEMOUTH SHOW.—A lady exhibitor thus writes to me:—"The Bournemouth Show was held in February, 1876, and I there took a second prize. After many months had elapsed (quite six I should say) I wrote to the Secretary,

but received no answer to any of my letters. I then wrote to the Treasurer, and from him I received a most courteous reply, saying that he was astonished I had not received my prize money, and that he would write to the Secretary. My solicitor also wrote. The answer then came that he had no money. Doubtless there are many sufferers equally with myself, and I think we should join together and get some redress. I certainly think that before they get up another show, as I see they are about to do from 'our Journal' of last week, they should pay off old scores." So far the lady. Permit me to add that surely this is a very disgraceful case. Nothing is more calculated to ruin shows than such proceedings. Exhibitors doubtless will remember the proverb, "Once bitten twice shy," and be very shy indeed of showing at Bournemouth. Perhaps the Secretary may be able to clear up the matter and put all straight.—WILTSHIRE RECTOR.

AQUARIUM POULTRY SHOW.

BEFORE criticising the classes we must speak of the faultiness in the arrangements. It is no good to cloak matters, and had the Show been a local or country one long and loud would have been the outcries. It seems hardly credible when the Show opened on Tuesday at 2 P.M., that on Wednesday at the same hour, twenty-four hours afterwards, not only were the cards not up in very many classes, but it was impossible to find out the winners. We had to send news to distant friends, and could not find out who had won. It is ridiculous for the Committee to say that the push was so great that they could not get the work done, for the Show after all was only a moderately-sized one. We have had to help in the management as far as we could, and also and we think that the cards could have been placed on the pens at a much earlier hour. A regular *bouleversement* happened, too, among the classes each Judge was to adjudicate upon, and after Mr. Tegetmeier was announced to judge the poultry we cannot see why he was put to the Pigeons. Then many birds fought terribly for want of proper pen divisions, and exhibitors on Tuesday were seen running here and there with food and water for their neglected birds. These things combined will, we should think, make many shy of sending to this Show again under the same management. It is a sad pity, for the room is so well and evenly lighted, and the place itself so convenient of access. We are sorry to have to grumble so much, but the things we complain of were on everyone's lips. We believe the birds were speedily dispatched at the close of the Show which was that remaining point—as we hear of many who received their birds home in excellent time.

BRAHMAS.—Dark (cocks).—This was a poor class. The third-prize bird we considered in many points the best, but he has an ugly white patch on his breast, which doubtless lost him the first honour. We were very much surprised that we did not see Mr. Lingwood's name in the catalogue. Hens a much better class. First a beautifully pencilled pullet, rather small and deficient in cushion. Second and third large well-marked hens. Light, in spite of their four prizes and the good money value, failed to make a better show than Dorkings, Spanish, or any other less favoured breed. The cup went to Mr. Horsfall. We candidly confess we did not care for the award, and we feel sure he is not the champion bird, for he has neither the width, shape, nor feather of that cock. Our own choice was for the first prize bird, and if the fourth had even had the first prize we should not have said a word. These were two good birds, shapely, large, and well feathered. Second we did not fancy either. He had not the shape we like for the breed; he had, too, an immense tail, and we did not like his colour very much. Hens we thought on the whole carefully placed. First was a large bird but pale in head and looking a little out of condition. Second was the pullet which was protested against at Wolverhampton. She is undoubtedly a pullet, and a grand one to. Third was an excellent hen, large and good in shape; while fourth went to a capital bird, but too dark in hackles for our taste, still a finely-shaped bird. Mr. Leno sent a beautiful pullet which, perhaps, ought to have come in somewhere. Mrs. Tindal's bird, too, was shapely, but seemed quite ill and out of condition. In the £5 5s. class a well-shown pen came in first, but we noticed no very striking pen, and should consider the class a failure, there only being nine pens for the £5 worth of prizes.

SPANISH made two excellent classes, and Mr. Howard was very happy we thought in his selections. In cocks the winner was a good bird; his comb was capital, and his lobe fine and open. The second also had a beautiful face, but seemed a little high in the tail. We even thought he was a little round in the back, but the Judge told us he had handled him, and that this was not the case. Third went to a good cockerel, well shown and large in lobe. The hens made a fine collection of face and comb. She pens. The first was a superb bird, good in face and comb. She was shown in lovely form, and would probably have had the cup had it not been for a small fold on one side of her face. Second and third went to fine pullets, well shown and well

plac'd. Mrs. Allsopp's bird in pen 261 was a remarkably good hen, but she had a small piece torn on one side of her face, which kept her, we suppose, out of the prize list. The Spanish cock went to the cockerel.

FRENCH made but small classes. *Houdan* cocks were poor, and we did not see a comb in the class we really liked. Hens were much better, and Mrs. Vallance scored another triumph for her grand old hen, which, as we have before stated, is our *beau idéal* of Houdan markings. Second was also a well marked large hen, as was the third, but the latter did not look quite so bright as the first prize bird. We were sorry to notice that the Rev. W. Pearson's cockerel had had his tail injured, apparently by having the chief tail feathers cut right across in the middle. In *Criève* cocks the first won easily. He is lustrous, large, and well shaped, but poor in head. Second was a good bird, but not so large as the first. *Criève* hens only numbered six. The first good in shape and size, but not very pretty in crest. Second and third were fine hens, but not in their best looks. Miss Arnold sent a slate-coloured hen, which was good in points, and we thought deserved some notice.

GAME had six classes and eighteen prizes, half of which and the cup were monopolised by Mr. Matthews. The cock was a fine old dark bird of splendid shape and bright colour. The chicken from the same yard, which won second, closely, however, pressing on his heels, for he was a stylish bird with capital crest and splendid feet. The first hen in *Black Reds* was a shapely bird, and good in colour. Of the *Brown Reds*, as a lot, we thought the cocks the most superior, but the winning hen was a fine one in hard feather. In the next cock class good *Duckwings* were first and second, while a yellow-legged *Pile* of quality won third. In hens the winners were all *Duckwings*. The first a pullet of much merit, sound in colour and in fine condition.

MALAYS with fourteen pens were a fine lot, first once more going to Mr. Lecher. The cock is a good one, but we fancied either Mr. Penny's or Mr. Stanley's hen before his companion. We liked too Mr. Brauford's pair. Mr. Joint sent two good pens, but badly of as good colour as the winners.

LEGHORNS had two classes, in which were seven pens of Browns and five of Whites—no very great matter. We thought in Browns the winning pair were the largest; they had good combs and earlobes; the second also were a smart pair. Whites were not quite so good, and we did not much admire the colour of the first cock, but in other respects he was a good bird.

ANDALUSIANS were moderate. Nine of the eleven entries belonged to Mr. Fry and Miss Arnold. We thought there was an inclination to high tails here as in Leghorns, but the winners were apparently well chosen.

SILKIES made a pretty little collection. The winners we liked much, and we placed them in that position before the cards came round. Second contained a sweetly pretty cock, but a poor hen; and third were but moderate in claws and crest, but had the pretty turquoise blue ears. The judging gave us the idea that combs on the cocks had been taken more into consideration than anything. We have always made a great p. of this feature, but we do not think for it claws, crest, and silkiness should be disregarded. Mrs. Holmes's highly commended pen was rather coarse or else good. Mr. H. Dean sent a pretty pair, but one bird had a crooked toe.

The Variety class was a good one, La Flèche winning first and Cuckoo Cochins second honours. There were also other good birds of this latter variety and another excellent pen of La Flèche. We saw, too, some Black and White Micoras and a pen or two of the "wild Turkey's" connections.

The Sale classes as a lot we thought remarkably poor. We noticed one or two fair Light Brahmas, a sound coloured pair of Buff Cochins hens of Mr. Darby's, and a good pair of White Cochins being the only good ones among all the three first prizes. The French Silling classes were but meagrely filled, but the fact is by now most fanciers have either disposed of or have eaten their surplus birds, and purchasers are mostly snited.—W.

DORKINGS.—Coloured good classes. Cocks—First and cup (Parlet) a well-shaped bird with good feet. Second (Barrell) appears to have been recently fighting, but the accident did not deprive him of his position, which we thought he justly deserved. Hens.—Parlet again first with a fine bird, second and third also good. *Silver Greys* a capital class. The competition between the first and second was very close. Tuir'd a nice pen. Cuckoos pleased us very much. Nine entries, nearly all good. The improvement that has been made in this variety during the last two years is very satisfactory. Whites a small class of five. The winners were an exquisite pair, and well deserved the cup.

COCHINS.—Buffs (cock).—First a grand bird, beautiful in colour and well feathered; second and third closely pressed by pens 62, 63, and 67. *Parlets* (cock) a moderate class. The prizes we awarded were justly distributed. Hens were superior to the cocks. Mr. Wood exhibited three splendid birds. The first was the largest and perhaps the best shaped; but the pullet in the adjoining pen (90) was much more clearly marked

on the breast, and equally as well feathered in the leg. Pen 88, the same owner, we also thought deserved a position. Whites were a very beautiful lot. Some little fault was found with the buckle of the hen in the winning pen, but we thought the Judge's awards correct. Blacks were fair. They appear to have found many new friends, and we trust the ensuing season will show some marked improvement.

We thought the HAMBOURNS very good classes as compared with the average standard of merit through the show. *Golden-spangled* (eight entries).—The cup went to the first pair in this class. The cock is a lovely bird in carriage; but part of his breast almost too heavily spangled to please us. Second a small and neat pair, very even in mooring; third a very narrow-combed cock with blueish lobes, and a hen somewhat mottled in spangling though bright. *Silver spangled* (seven entries).—First and second were two lovely pens, splendidly shown. The cocks' sickles were singularly well spangled, and their hackles beautifully white. The first cock was the best in carriage; but in some points we preferred the second hen. The third-prize pen contained a very fair cock, but his comb, we fear, not as nature made it; and a beautiful hen all round. *Golden pencilled* (twenty-one entries), a capital class. This is now everywhere the best and most-filled class of Hambourgs, we fancy because they are so much more easily bred to than the first pair in this class. The cock is a lovely bird produced from the same pen if only judiciously mated. The first cock was neat in head and even in colour, but with ugly bars across his sickle; the hen evenly marked on a good ground colour. Second a good cock, and a hen rich in colour but rather coarse in marking. Third not a good pullet—badly marked on the breast; but a capital cock with a well-laced tail. Mr. Holdsworth's very highly commended pen contained a cock with fine carriage; and Mr. Crosswell's highly commended pen a very pretty pair all round. *Silver pencilled* (seven entries).—This variety is certainly at a low ebb. The only really good pen was the first, the cock of which had a beautiful tail. Second was a cock terribly out of condition, with reddish lobes but well laced tail, and a very fair hen. Third were not well shown; the cock had a good tail but bad comb. *Black* (sixteen entries).—These were most unfortunately placed, some of the pens being at one end of the building in a capital light, the rest at the other end almost in darkness. First was by far the most lustrous and green cock we ever saw, with very fair carriage; the hen pretty in shape but rather purple than green. Second a neat and good pair all round, but in the bad light. Third only a fair pair; the hen very bad in comb. Mr. Serjeantson showed two capital pairs, one apparently quite equal to the first-prize pair; but unfortunately they were pened after the Judge had gone round.

POLISH. *Golden-spangles* (seven entries).—The first pair were large in crest; but the hen's crest was almost white. The cock was, for the breed, in good plumage, with a dark tail, and his markings really incline to spangling. Second a cock with crest better in shape than the first, and a prettily laced hen; but generally inferior to the first pair. Third a cock with enormous crest thrown too far forward, and a hen too heavy in marking. *Silver* (four entries).—First a very nice pair; but we do not like a cock's tuft so much over in front. Second were a pair with very well shaped crests. *Black or any other variety* (eight entries).—The Polish cock won for Mr. Norwood's pair of Blacks first in this class. They are now well known and remarkable for their well-formed crests. Second another beautiful pair of Blacks; the cock has a splendid crest, and the hen is a perfect bird, though her crest does not seem to have fully expanded since the moult. Well it may not do so, as we believe she is eleven years old! Third Black again; the cock's crest a little rough in front; the pullet was, we think, the first Birmingham bird, with a splendid tuft for her age. One poor pair of Buffs put in an appearance.

BANTAMS.—Game, *Black Red* (fourteen entries).—The birds in this class were generally too large. The cup pen, however, were a lovely little pair, the cock capital both in style and colour. In the second pen was a cock not well dubbed and swelled about the head, with a hen far too dark; third were large; fourth pen contained the second best cock in our opinion, but a mosty hen. *Brown Reds* (five entries), were all large and not a good class. The second-prize pair were much the smallest, but the cock carried his tail badly. Fourth were good in carriage but very big. *Any other Variety* (nine entries).—First small *Duckwings* good in style, the cock's wing colour mixy; second *Pile*, the cock good, hen too large; third *Duckwing*; fourth pretty *Piles*, which we should have put higher. *Single Cocks* (ten entries).—First a beautiful little Black Red; second another equally good in form but much larger; third a fair *Pile*; fourth a *Duckwing*. *Black* (thirteen entries).—First a neat pair, but rather devoid of sheen; second rather big but good in gills and stylish; third large again, the cock very bright, but his tail feathers too broad. *Silbrihts* (ten entries), were not so good as we have seen them. The cup pair were *Silvers*; the cock very good, the hen too lightly laced. Second *Golden*; the hen a model of loveliness, but the cock too heavily marked. Third

Silvers, small and well faced. We suppose a little mousing on the cock's tail went against them, otherwise we thought them the best pair. *Any other Variety* (seventeen entries), were a capital and most interesting class. First a pair of White clean-legged, better than any we have seen for a long time. Second, White-foot-d, nicely shown. Third, a perfect little pair of Pekins; the hen, perhaps, was not quite so Coochin-like in style as the cock. Mr. Phelps and Mr. McCrae showed good pairs of Cocks, and Mrs. Holmes a pretty pair of Black-footed.

Ducks—*Aylesbury* (seven entries).—First a very large pair and not over-fat-l; second a good drake but a dreadfully fat Duck; third fair birds. *Rouens* (twelve entries).—The cup pair were a magnificent Duck and a drake which looked unhealthily in throat and bill; second a good pair; third a good drake and a Duck showing too much white on the wing. Mr. R. Gladstone's very highly commended and highly commended pairs looked healthy and fine. *Blacks* (fourteen entries).—First were very small and decidedly the best pair; second were large but very lustrous. We did not think the third so good as one of this owner's very highly commended pairs.

ORNAMENTAL WATERFOWL (seventeen entries), were a beautiful and most attractive class. The cup went to Mandarins, small and good in all their points. Second fanciest Carolinas, the Dorchester cup pen we fancy. Third the well-known Karkas or Paradise Ducks. Among the very highly commended were a pair of the new Pekin Ducks and small Egyptian Geese—C. The judging, we believe, was divided thus:—Mr. Tebbay the Game, Game Bantams, Sikkira, Malaya, and Hamburgs; Mr. Hewitt, Dorkings, Cochins, and Waterfowl; Mr. Nicholls, Dark Brahmas, French, Polish, Leghorns, Andalusians, and the Variety class; and Mr. Howard the remaining poultry classes.

PIGEONS.

HAVING spoken of the Show generally last week I now come to particulars.

Pouters come first, an arrangement which I have noticed to be on the increase, and I think these very tall birds deserve this position. Their pens are higher and wholly different in shape, and the formation of the bird is so peculiar that it, attracting the instant notice of non-fancier visitors, deserves the first place. *Blue pied cocks*.—First a bird of Mr. Fulton's (854), well shaped, but legs too forward and not over clean in plumage. S. second, 860 (Watkin), a good bird with wondrous long legs. Third, Fulton, No. 858, belonging to Rev. W. J. Burdett, was the best cock in the class, a pure Blue without a tick, and with a good bar, but he seems to be a pity thing. *Black and red cocks*.—First and cup (Wroct) a good style and a good shape, and superior in slenderness to the general run of Blacks. S. second another good bird (Fulton), but crop loose. Third (Fulton), a good all-round bird. Yellow or Red cocks.—First (Herrieff), a Red and very fine, with vast crop; this bird was all but winning the cup. S. second Mr. Fulton's Yellow, an old friend. Third a Red (Gill), the best Red as to colour in the Show, but deficient in crop: the colour with a good crop would win first everywhere.

Mr. Gill had also a large Yellow but somewhat thick; he deservedly had a v.h.c. *White cocks*.—A very good class indeed. First the best White Pouter now alive. Second (Baker) a thoroughly good bird; so, of third and of the four others noticed, *Pouter hens*—Blue pied.—First (Fulton) a very charming hen, bishoped on one wing and pretty playful; but, as if she knew her fault, kept the best wing to the front. Second (Baker) very good colour and half moon. Black pied hens.—First and cup a very elegant slender hen of Mr. Fulton's, very rightly placed. Second (Baker), over gay. Yellow hens, an excellent class. First (Fulton), good colour and crop. Second ditto in every respect save colour, it being red. Third a Yellow. Another Yellow, v.h.c. Mr. Baker had a very large-cropped bird, a Red, which had an n.c. *White hens*.—First Mrs. Ladd's White, which she may be gratified to hear is considered to have more than taken the place of the bird that died coming from Edinburgh. The Judges and fanciers agree in their estimate of the grandness of this bird. Second Fulton, third Baker. Mr. Heath's commended bird will yet do better. The Pigmies were chiefly noticeable in being Blue hens of the beautiful colours, one a Black pied and another a Blue pied, both good attempts and deserving praise for the pains and skill bestowed.

Carriers.—Champion class for cocks over one year; and mark, every one of these birds to be eligible for admission must have won not less than three first prizes of £1 each. Six birds were found equal to the occasion, and Mr. Eckroyd's bird with enormous wattle above and below stood, as he must stand, first. Mr. Maynard had the honour of breeding this Carrier. Next came the non eligibles for the champion class, being the Black cocks separated from the Duns. First Flicker; second Heritage, a good Pigeon; third Chandler. *Dun cocks*.—Cap Fulton, second Baker. Other classes followed, the Black hens being very superior; and the first Dun (Eckroyd) a particularly nice colour and with even flight. The young Black cocks were regarded as excellent. I believe the Judge wishes it to be known that he at first threw out Col. Hassard's birds, judging them not

bred in 1876, thinking them older; but afterwards he was convinced they were genuine young birds. These young class as were very good.

Dragoons.—An old and good fancy now revived and wondrously popular, a popularity which even Antwerp has not been able to effect. The great prizewinner of the day is certainly Mr. E. Woods. The most valuable prizes, whether I or Blues, Yellows, Silvers, Chequers fell to Mr. Woods both in cocks and hens. But readers must not conclude that his birds only were good, far from it. Almost every Blue cock was good; so of many Yellows. Indeed so even are the Dragoons now at large shows that only little points decide.

Short-faced Tumblers.—The Almonds were not very numerous and many of them did not please those close critics Almond fanciers; Mr. Eckroyd's cup cock and Mr. Baker's rich hen, first prize, excepted. The Shortfaces not Almonds was a little more numerous than usual, even in the Black Mottled class. Mr. Henning's two best birds, the cup and second prize, were very charming, followed well by Mr. Baker's third. Bald and Beard Shortfaces were fairly numerous. First Mr. Woodhouse, a Blue Bald; second Blue Beard, same owner; third a very rich-coloured neat Red Bald. Mr. Reddock had two good Black Bards, and Mr. Murphy a good Red. Among the other Shortfaces Agates were the winners, and Baker and Fulton their owners.

In Barbs the good old names of P. H. Jones and Maynard stood high. The former gentleman has been one of the steadiest fanciers of this class for a great number of years.

Jacobins.—Conceded that the one general remark may be made, viz., that the length of the chain feathers from back to front has visibly increased of late, but a little break in the top of the hood will make its unfortunate appearance still. Oh, that ugly gap! The cup Red cock was a charming exception. Second Red cock (Fulton), as good a bird save in hood. Third (Baker) short face and good long flights, quite the Jacobin shape.

Yellow cocks.—First (Fulton) very good, but not equal to Reds in hood, though not bad even in that point. Second (Frame) rather too loose in mane. Third (Heritage) very good. Blacks.—These will come too long-faced. First (Baker) small, neat and good flights; second good long bird, bad hood; third very good flights. *Jacobin hens*.—Reds: First (Fulton) neat and small, and yet good Jack points. Yellow hens: Cup (Frame) very exciting. Conceded that the one general remark may be made, viz., that the length of the chain feathers from back to front has visibly increased of late, but a little break in the top of the hood will make its unfortunate appearance still. Oh, that ugly gap! The cup Red cock was a charming exception. Second Red cock (Fulton), as good a bird save in hood. Third (Baker) short face and good long flights, quite the Jacobin shape.

Yellow cocks.—First (Fulton) very good, but not equal to Reds in hood, though not bad even in that point. Second (Frame) rather too loose in mane. Third (Heritage) very good. Blacks.—These will come too long-faced. First (Baker) small, neat and good flights; second good long bird, bad hood; third very good flights. *Jacobin hens*.—Reds: First (Fulton) neat and small, and yet good Jack points. Yellow hens: Cup (Frame) very exciting. Conceded that the one general remark may be made, viz., that the length of the chain feathers from back to front has visibly increased of late, but a little break in the top of the hood will make its unfortunate appearance still. Oh, that ugly gap! The cup Red cock was a charming exception. Second Red cock (Fulton), as good a bird save in hood. Third (Baker) short face and good long flights, quite the Jacobin shape.

White cocks.—First (Fulton) very good, but not equal to Reds in hood, though not bad even in that point. Second (Frame) rather too loose in mane. Third (Heritage) very good. Blacks.—These will come too long-faced. First (Baker) small, neat and good flights; second good long bird, bad hood; third very good flights. *Jacobin hens*.—Reds: First (Fulton) neat and small, and yet good Jack points. Yellow hens: Cup (Frame) very exciting. Conceded that the one general remark may be made, viz., that the length of the chain feathers from back to front has visibly increased of late, but a little break in the top of the hood will make its unfortunate appearance still. Oh, that ugly gap! The cup Red cock was a charming exception. Second Red cock (Fulton), as good a bird save in hood. Third (Baker) short face and good long flights, quite the Jacobin shape.

Fantails.—Two divisions, English and Scotch. Former, cup (Maynard) was like a man with Scotch blood that will show. Others were regular large, flat-tailed English birds. The graceful little Scotchies have improved in fall of late. In fact the two nations have joined, and each are the better. A very pretty pair of Black Saddlebacks took a first prize in the other coloured class. Next to the White these are the handsomest Fans.

Nuns.—A little more numerous, and a Scotch fancier all the way from pretty Montrose deserved and won the first prize. Some of these birds were very dirty.

Trumpeters.—Mr. Hutchinson's magnificent Mottles won the cup; the best birds in the fancy.

English Owls.—The champion class, like all champions, small but so good. There were in all fifty-three English Owls to nineteen foreign. The former seem to be now the favourites, but I hope the latter will be cherished, for they are among the most lovely and are the smallest. *Pigmies*.

Turbits.—Blue, Silver, Red, and Yellow. The prize birds, especially Messrs. Eckroyd and Salter, very superior. In the small class of any other colour the first was a good Black and a pretty Pigeon, but with a head like a mouse. No. 1607 very superior in this point.

Maggies bid fair to be more numerous than the bird from which they take their name. Singular is the fate of Toy Pigeons. A very few get into lasting favour, many new birds come and soon disappear. Mr. Salter's Yellow cup bird was singularly good and neat. As good Msqs are shown of the three colours Black, Red, and Yellow, what a pity that a still older bird the Nun is not so fortunate.

Swallows and Archangels next. Mr. Long's first Red Swallow of a very rich colour; and Mr. Tedd's second, black in colour and very correct markings. With Archangels it is a case of standstill: pity this.

Runts, the aldermen of Pigeons, on the increase. Amusing very was it to see the big things cuddled up in handkerchiefs and pinned to the table. Not that they resisted, no; but they have easy tempers. "Is your little bipeds feathered or unfeathered

that are pappy. The very d serving, because infinitely amusing classes, Flying Tumblers, were large and good.

Balds or Beards.—First good, clean-cut, old-fashioned Black Bald, neat as wax. Second an equally old-fashioned Black Beard. Third a Yellow Beard. The Any other colour still better, but to get pretty birds and good colours there has been too much crossing with the Shortfaced. Judges! look out. Let this class be true to its name, not a mere resort for carelessly bred Shortfaced.

In the *Any variety* class Frillbacks now seem to predominate. A pair of those uncomfortable-looking birds Lace Fantails took second. I was pleased to see a pair of Turbintens, one being very good. Antweps, Short faced and Homing, followed, and two good Selling classes, £3 and £2 in price, followed, and a Flying class of Homers finished the Show.

I am inclined to think that all the printers in London and for many miles round were on the strike, for even on the second afternoon of this Show no prize list was printed—a thing that has never occurred during the fifteen years or so that I have attended poultry shows. It was a matter of relief to me to find that daily newspapers were still printed. Indeed, indeed, this late news was too late, for the London show does this and kindred faults will be avoided.—WILTSHIRE RECORD.

P.S.—Is it possible that the fish at the Aquarium were by mistake fed on Tuesday on the prize cards, and on Wednesday on the prize lists?

POULTRY.

DORINGS.—Coloured.—Cock.—Cap. F. Parlett, 2, T. C. Burnett, 3, J. Copples, Hen.—1 and 2, F. Parlett, 1, T. C. Burnett, 2, J. Copples, 3, W. A. Barnell, 4, W. R. Wren, 2, O. E. Cresswell, 3, T. C. Burnett, Blue of Cuckoo.—1, Mrs. H. Allen, 2, H. L. Playfoot, 3, Virgo & Son. White.—Cap. O. E. Cresswell, 2, R. A. Bonnier, 3, Miss Ashurst. Selling Class.—1, J. L. Lowndes, 2, G. Ellis, 3, Major W. Plimmer.

COCHINS.—Buff.—Cock.—1 and 2, G. H. Proctor, 3, Mrs. A. Tindal. Hen.—Cap. G. H. Proctor, 3, Mrs. A. Tindal, 2, W. A. Barnell, Partridge.—Cock.—1, A. Aspden, 2, Mrs. J. Hendon, 3, R. F. Povey, 4, J. Wood, 5, J. Wood, 6, W. Smart, Hen.—Cap. R. J. Wood, 2 and 3, E. Tindal, Hen. v. R. Wood. White.—Cap. R. F. Percival, 2, Mrs. A. Tindal, 3, A. Darby, Hen. v. R. A. W. Ward, 3, Mrs. A. Tindal, 4, R. F. Percival, 5, A. Darby, 2, A. Darby. Selling Class.—1, Mrs. A. Tindal, 2, H. W. Reville, 3, A. Darby, 4, Mrs. A. Tindal, 5, Mrs. A. Tindal, 6, J. F. Smith, 7, Miss E. C. Shuter, 8, E. Fitchard, Hen.—1, Mrs. E. C. Shuter, 2, Rev. J. D. Peake, 3, T. F. Ansell, 4, W. R. Garner, Hen. v. Rev. W. Pearce, J. F. Smith. Selling Class.—1, Mrs. A. Tindal, 2, M. Leno, 3, W. Jacob, 4, A. Comyns, Jun. Light.—Cock.—1, E. C. Horsfall, 2, F. Smith, 3, R. F. Broome, 4, R. F. Broome, 5, Hen.—1, J. Birch, Jun. 2 and 3, P. Hamae, 4, Miss Lae. Selling Class.—1, Mrs. A. Tindal, 4, J. Hamae, 3, W. Teed, 4, H. Mitchell.

WYANDOTTES.—Copper.—Cock.—1, W. C. Rogers, 3, E. Jones, Hen. v. J. W. Wynn Hen.—1, J. Boulton, 2 and 3, E. Jones.

FRENCH.—Houdans.—Cock.—1, G. D. Harrison, 2, Mrs. Wilson, 3, L. W. Thomas, Hen.—1, G. D. Harrison, 2, Mrs. Wilson, 3, L. W. Thomas, 4, Mrs. Wilson, 5, J. B. Brown, 6, W. Cutler, Jun. 7, H. Stephens, 8, J. A. C. Barrill, 9, J. Mackell, 10, J. M. Malen.

PERCEPES.—Cold-spangled.—Cap. G. J. Duckworth, 2, J. Rawnsley, 3, T. Deau, Silver-spangled.—Cap. G. J. Duckworth, 2, J. Rawnsley, 3, G. Percival, 1, C. Judson, 2, Miss D. Mackenzie, 3, Duke of Sutherland, Hen. v. J. K. Castell, W. K. Tinker, L. Holdsworth, Silver-pencilled.—1, Dr. E. Snell, 2, Duke of Sutherland, 3, Ferris Bore, Black.—Cap. W. Clarke, 2, W. E. George, 3, J. Ross.

GAME.—Black Red.—Cock.—Cap and 2, S. Matthews, 3, W. J. Pope, Hen. v. H. George Hen.—Cap. W. J. Pope, 2, W. W. Wadsworth, 3, G. Stapleton, Brown Red.—Cock.—1 and 3, S. Matthew 3, H. E. Martin, Hen. v. H. Martin, 2, W. Watson, 3, W. Watson, 3, W. E. Martin, Any other variety.—Cock.—1 and 2, S. Matthew, 3, S. Matthew, 4, S. Matthew, 5, S. Matthew, 6, S. Matthew, 7, S. Matthew, 8, S. Matthew, 9, S. Matthew, 10, S. Matthew, 11, S. Matthew, 12, S. Matthew, 13, S. Matthew, 14, S. Matthew, 15, S. Matthew, 16, S. Matthew, 17, S. Matthew, 18, S. Matthew, 19, S. Matthew, 20, S. to deprive a strong stock of bees of their stores. When the brickwork was cut away what a sight presented itself! One large flue, its diameter completely filled-up with enormous combs thick and heavy. This appears to have been the breeding space, for the bees had passed through a very small hole in a partition-wall and built magnificent combs in an adjoining flue, the greater part of the combs were filled and sealed-up. The man informed me their depth and breadth were such that as he cut them out and handed them down a ladder, he could only compare to "fitches of bacon." Another stock which had taken up their quarters in the roof of a thatched cottage was deprived of their stores about the same time, and was reached by cutting away the ceiling of a bedroom. The combs were taken out the outside of a brick chimney which passed through the roof and into the sky. There were supposed to have measured many of them about 2 feet by 2½ feet, and of great thickness, and as they were cut away were handed down and stacked into tubs, pans, dishes, bowls, and every available vessel to be found. Unfortunately the weights of neither stock are known, but the produce of the two could not have been much short of 400 lbs., and perhaps considerably more. It would appear to most common-sense people that these two stocks of bees were strong and healthy, and had abundance of honey at easy distance, and good weather to collect it, and plenty of store room. Will your correspondent tell us that this chimney-stack and cottage roof had "form, material, and construction" inferior or superior to the best hive ever made? While some talk of wood versus straw, why should not I ask, Then what about bricks and mortar if mere weight is all we have to consider?

Your correspondent seems singularly unfortunate in the shape and working of his skeps, and would have us (your reader I mean) believe that a glass only can be placed to super them, and that, too, in a very bungling manner. In all humility I would recommend a leaf or two out of Mr. Pettigrew's book to his notice. I can put on my large straw skeps boxes belonging to any hive, bell-glasses, or, what I prefer, straw supers 4 inches deep and from 8 to 18 inches over, flat-topped, very strong, and having a 3 or 4 inch hole in the top, which is covered with a piece of glass, then woolen, and a thin piece of board, to enable me to report progress when the bees are not wanted to go higher.

Your same correspondent on page 109 writes, speaking of convincing a straw hivist, "To be sure I had an advantage over him in possessing the Italian bee." Is this an advantage? I ask this of anyone who will kindly give the information through the Journal, because it ought to be settled in what respect they are better, equal, or worse than the common bee. A few years ago I had decided to give £5 for a good stock of Italians, and I went to Exeter to see the good Mr. Woodbury and his apiary, who very kindly offered me a veil. "What is that for?" I asked. "To put on your face; it is safer for both of us," he said. Then he proceeded to take out his bar frames, beginning with the Italians, pointing out all the little matters of interest. "See how these Italians sail about us," he remarked, as he held up their combs for inspection; not so the black bees, which we got next. These were examined in the same gentle and systematic manner, and exhibited their irritable temper a little, but nothing compared to what I have seen since when changing floor-boards. "Now, Mr. Woodbury," I asked, "will you be good enough to tell me in what respect are these Ligurians superior to the common bee? All things being equal, will they collect and store more honey?" "No," was the reply, and his emphatic "no" decided me. "Then in what way are they superior?" I asked. His reply was, "Only that they are less willing to use their stings." From that day to this I have never possessed an Italian, but should be pleased to do so if there is any good in them which the common bee does not possess. If that was the decided conclusion this great question had come to, where now lay their superiority?

One more important question I asked of this gentleman—namely, "Will bees collect and store a greater weight of honey in your bar-frame hives than in a common box 14 inches by 14 by 10, and supersed as required?" "No," was his answer; "but my hives may possess other advantages." Certainly, and thanking him very much I took leave of Mr. Woodbury, much pleased with the interview. I may mention that at that time all my bees were in boxes as above, Nutt's hives, and Stewarton, all of which I have still.—W. J. C.

CRUDE HONEY AND THEORIES.

Your esteemed correspondent the Vice-president of the Caledonian Apiarian Society was kind enough to publish in your number for the 14th December some notes of a visit he paid to my apiary during last summer, and he referred to the opportunity which he and the two keen entomological friends who accompanied him had of inspecting the procedure of the honey-laden bees as they arrived and deposited their loads in the comb cells of my observatory, which carried conviction to the minds of my friends of the unreasonableness of the "twice-swallowing and disgorging theory" which Mr. Pettigrew has maintained with

a pertinacity worthy of a better cause. There was a sectional portion of comb in the upper part running parallel to and wrought on the glass, thereby showing a half comb, the divided side being next the observer, which I had allowed to remain on as a special treat to my visitors. From its central backbone the cells were attenuated and carried out on either side to a depth requiring three and four separate divisions or "bulk-heads," to use a nautical phrase, and the marked contrast in colour of the different honeys stored in each, with the uninterrupted view of the head of each bee while discharging the secretion, elicited expressions of the greatest interest and delight from my friends.

To account for the difference of opinion on this and many points in the natural history of the bee, for the benefit of the general reader it becomes necessary to explain that parties who keep bees in domiciles with fixed combs are of necessity on such points in the dark, the hive being to them a sealed book, hence the tempting opportunity for the exercise of a lively imagination and the guesswork of fiction to set against fact. They deny the toiling labourers their well-earned repose; they suppose them busily employed during the silent watches of the night in moving about the eggs which the queen has improperly deposited, changing their sex by a process without a parallel in animated nature; and, heaviest task of all, removing to a different portion of the hive the entire gleanings of the day, and restoring it a chemically changed substance, robbing out little favourites of half their heaven-born instincts. These crudest of crude theories disappear like "the baseless fabric of a vision" when the bee-keeper advances from "fixism" to "mobilism." The precious truth is then laid bare.

The workers are never seen to "set" or move the eggs about, although rarely they may eat them when pressed by want. The queen does not drop them at haphazard; she thrusts her head carefully into the cell in every instance, and on satisfying herself on its thorough preparedness then deposits the egg, fixing it in position by that familiar half turn she never omits. The honey-laden bee is seen to carry the nectar of the flower right up without any intermediate resting-place for security to the super or uppermost portion of the combs, and hurry off for more till the cell is filled. Then what follows? Is it moved to another portion of the hive? Never, there is no such superfluous waste of labour in the hive. It stands a time; the watery property (proportioned to the state of the atmosphere and weather) rises to the surface and is sipped off by the workers, and the final extraction made through that little central orifice of what I described three years ago as the "aqueous and aerial" properties, before it be hermetically sealed-up. When at that time describing the process as above, your correspondent Mr. Pettigrew pronounced my fact as unworthy of a place "at the top of the list" of theories; but fortunately its truthfulness was subsequently confirmed by a special experiment instituted by that most excellent correspondent "R. S.," whose graceful contributions to these columns are much missed by us all.

The separation of the watery element takes place somewhat after the style adopted by a clergyman's lady of my acquaintance, who, strongly suspecting some twitches of the iron-tailed cow in her milk supply, put aside a simple tumbler for a time, set it on a plate, and astounded her milkman at the door as follows:—"Here is your milk; if you intend to give me this quantity," pointing to the thicker strata at the bottom, "in return for my money, well, I'll just take it; and please allow me to flavour it with this," pointing to the water floating on top, "to my own taste for the future."

Many years ago I had an observatory stock placed in a staircase window, which stood much in want of feeding, and feed it I did with no stinted hand. Owing to its inside position and consequent warmth of the house they took down greedily. The exposure was from where

"Foreas w' his blasts did blow"

so vigorously in at the entrance that not a solitary bee dared venture abroad, placing my little favourites in a most unenviable plight with their loaded sugar-syrup combs. The wind chopped round at last, and the sun shone out brilliantly. The extracting process began with a vengeance—the pent-up prisoners came forth like a vengeance, and at their high altitude could be seen disporting themselves backwards and forwards over a bit of lawn like madcaps, at the same time emitting in long jet-like clear streams crossing and recrossing each other, which could only be compared to a sweetened shower.

I cannot close these remarks without impressing on the novice the great necessity for the careful keeping separate and distinct for running the unsealed from the sealed combs. The contents of the latter will consolidate and keep even at midsummer; that of the former should always be scrupulously kept out, otherwise the smallest quantity acts "like the little leaven which leaveneth the whole lump."—A. RENFREWISH BEE-KEEPER.

IN MEMORIAM.—We regret this week to have to record the loss of another poultry fancier. Mr. H. C. Dear, of North Stoneham Park, Southampton, has passed away from us. He was one of

the first introducers of condiment for live stock, and his prepared meal was as successful with cattle as poultry. He has been in failing health a long time, and when we saw him at the last Bournemouth Poultry Show we thought him sadly changed for the worse. We understand his business will be taken on by his widow, at the great wish of the deceased. Besides being the manufacturer of these foods, he was an enthusiastic poultry fancier, and possessed some of the best blooded Game fowls of the day.—W.

SCIENTIFIC BEE-KEEPERS.

“SCIENTIFIC bee-keepers” is a term I and others have often used; but how few there are who deserve the name. The “science” of bee-keeping is scarcely born. Look at the bee of our day. It is the same as sung of by old Virgil twenty centuries ago. Regard our cattle, our poultry, our fruits and flowers, and contrast them with the stocks of a hundred years ago. The difference is marvellous. Our great grandmothers would not recognise the pullets they trusted or the vegetables they cooked as articles of the same genera. On these things science has truly been brought to bear. Patient selection of the best individuals, ruthless destruction of the worst, judicious crossing, and introduction of foreign varieties have made the products of our farms and gardens what they are. Why, then, should not like results be obtained by “scientific” culture of the hive bee? The introduction of the Ligurian bee was a step in the right direction, but this was twenty-five years ago—rather a long distance from the first step to the second. However the better qualities of the Ligurian may have been exaggerated, and they doubts have been, yet few who have given them a fair trial will gainsay the assertion that the variety is an improvement on our old black friend. No new discovery, for does not Virgil say—

“The better brood, unlike the bastard crew,
Are marked with royal streaks of shining hue.”

The world is wide, and in it are many species and varieties of bees; it would be strange indeed if we have absolutely the best. A bee having equal or better industrious habits to ours without a sting would be a very desirable acquisition; next to this, one disinclined to use her weapon would not be despicable, and such a character is possessed by the “kraimer” or Hungarian bee, which is slowly spreading over Europe, and has also emigrated to America. I also have a kraimer queen gradually gathering her children round her, whose characters I hope duly to chronicle. Great things are said of a bee from the Isle of Cyprus. A few of the leading German bee-keepers have this variety, and it is highly prized and jealously kept. At the Apicultural Exhibition at Strasburg, 1875, a queen was exhibited and sold for 75 francs to a professional queen-breeder, who advertised her progeny for sale during the ensuing summer. But it is never wise to count chickens before they are hatched. The queen died, and numerous orders for her daughters were unfulfilled. I have a conditional promise of a Cyprian queen next summer. This bee is said to far excel the black and Ligurian in profiencess and industry, but not to be commended for amiability. In the country round the Gulf of Cattaro dwells a bee very hardy and muscular; were they not so they would starve, for they have to gather their honey from the flowers which grow in the crevices and ravines of the mountains—high, steep, and exposed to rough winds. Their character is good so long as they are not disturbed, but if meddled with they become most wicked, stinging viciously and painfully. Perhaps these would suit our mountains and exposed coasts, where our native bee finds it difficult to support itself. But is it presumption to say that a judicious crossing of such varieties as I have named (for they are all believed to be of the same species) would improve our breed and enlarge our honey harvests?

A “RENFREWSHIRE BEE-KEEPER,” Mr. Phillips, and others have chronicled the splendid results of individual hives, or I may say the extraordinary industry of cert in worker bees, the daughters of known queens who above others in the same apiary have distinguished themselves by the excellence of their progeny. Common sense would tell us that here is a proper case for selection: weed out the other queens, and replace by the better brood. Experienced hands, as our friends here named, would find no difficulty in stocking the hives of a village from a favorite queen. In America this principle is recognised and practised. There is a bee in India which builds long combs pendent from the branches of trees. I have not the account to refer to, but I think the combs were described by Professor Wallace to be 6 feet long. India, in point of time, is not a far country now. Perhaps one of our compatriots on his homeward trip will some day bring us a live queen of this species, and some among us may live to see the day when the scientific bee-keeper may proudly say, “Look on this picture and on that.”—JOHN HUNTER, *Eaton Rise, Ealing.*

OUR LETTER BOX.

FRONTINO CAROLINA DUCES (E. K. L.).—Pinning them does not quantify them for exhibition; unpinned birds are the exception. Almost

all fancy wild fowl must be kept pinioned, or they must be treated as caged birds and enclosed on every side and overhead with wire or netting. Even birds bred tame will fly away in the winter if they are full-winged. There always remains enough of instinct in them for that; but if they are pinioned they remain. If there were any condition to be applied to the exhibition of wild fowl it should be that they should be pinioned, as that is the only state in which they can be kept.

BAR-FRAME HIVES.—J. G. wishes to know the best maker. These hives should be advertised.

STEWARTON HIVE (J. H. Etridge).—There are no entrances allowed to Stewarton colonies, except at bottom of the hive, half inch deep and as wide as the dovetail will allow, a central and one in each division on either side, making three in all, fully open during the heat of summer. Three 7-inch boxes are ample sufficient; 12 inches of breeding space in ordinary cases unless. A hive without an entrance is as convenient as a house without a door at swarming time. Thoughtlessly set down on a temporary board or table suffices the bees. Windows back and front, as at present, show through the state of the very excellent hives. Queens are checked in non-swarming stocks ofteor than is supposed. Here they are always detroned at the end of the third season at furthest. No winter packing is required with outside cover. Your friend will lose all the advantage of the set-riying system in his projected hive. The yield of hives is dependant on season and locality. Here swarms in colonies yield nothing the first season unless doubled.—A. RENFREWSHIRE BEE-KEEPER.

REMARKS.

- 21st.—Fine all day till 3 P.M., but then dull; a very slight snow shower in the night, which was observed on the 22nd.
 - 22nd.—Fine morning, but dull afternoon; rain began at 1 P.M. and fell at times during the rest of the day.
 - 23rd.—Fine morning; dull but fair all the after part of the day.
 - 24th.—Bally morning, but clearing up by 11 A.M., and fine during the rest of the day.
 - 25th.—Fair, but dull in early morning; but slight showers at intervals all day after 10 A.M.
 - 26th.—Beautifully bright and fine at 8.30, but in less than an hour snowing heavily, but only for a short time; fine afternoon and bright moonlight night.
 - 27th.—Very slight white frost at 9; a slight fall of sleet at 10 A.M.; but bright, though cold during the rest of the day.
- A fine bright week, northerly winds and lower temperature.—G. J. SYMONS.

COVENT GARDEN MARKET.—FEBRUARY 28.

TRADE is again quiet, and scarcely anything doing worthy of note. Good late Grapes are getting into a small compass, and are the only fruit that commands a really good sale.

From observations taken near London during forty-three years, the average day temperature of the week is 50.0; and its night temperature 32.4.

PEACH FORCING.—No. 7.

As the period of the year has arrived when forcing operations are in progress this subject may be seasonably resumed. I will discuss it under four cardinal heads—moisture, ventilation, disbudding, and pruning.

MOISTURE.—From the closing of the house to the flowers expanding the trees are to be sprinkled in the morning and afternoon, except when the weather is very wet and foggy, it being better in such weather to damp the floor and every available surface other than the trees, which affords sufficient moisture and is infinitely better than keeping the trees dripping with water. The evaporating troughs ought also to be filled with water, and should never be empty from that day forward to artificial heat being discontinued. My evaporating troughs are equal to about half of the extent of the heated surfaces of the pipes.

After the first blossoms expand syringing so far as the trees are concerned is, until the fruit is set and swelling, discontinued; but the whole available surfaces of the house are sprinkled with water in the morning and afternoon, which with the moisture constantly being evaporated from the troughs secures all that is needful for the maintenance of the blossom, for if the atmosphere be very dry, no moisture afforded by sprinkling or from troughs, it is certain that the best results will not follow. "Oh, but a dry atmosphere is necessary for Peach and other blossoms at the time of setting," some may remark. If by a dry atmosphere is meant such as we have in an unheated house, or one only heated so as to exclude frost or during bright fair weather when the trees outdoors are in blossom, I agree in the definition of a dry atmosphere; but the moisture in such houses (though no syringing be resorted to) and outdoors is fully equal to that of a house sprinkled twice daily and with evaporating troughs constantly giving off moisture. We must take into consideration the altered circumstances of trees started in November or December and dependant from first to last upon a temperature maintained by artificial heat. Instead of the moisture in the latter case being injurious I am certain it might, when there are no evaporating troughs, little piping requiring to be highly heated, and bright weather prevailing, be advantageous to the setting to syringe the trees occasionally. It is moisture in a measure that supports the petals and feeds the stamens. It is dryness which contracts and moisture which expands the pollen cases, causing their bursting and effecting fertilisation. With a parched atmosphere the petals soon drop, the anthers are lean, and a good syringing in such cases is often beneficial. It is not now my practice to syringe Peach trees whilst in blossom, for with the moisture had from the troughs and the sprinklings, I have in the brightest and most severe weather the moisture required, and to syringe would be to convert the pollen into paste, hindering instead of furthering its dispersion. What Peaches need at setting is a congenial atmosphere,

most but not stagnant. If anything a parching dryness is likely to be more injurious than a moist atmosphere or syringing; but the main thing is to keep the atmosphere whilst the setting is taking place from being close—stagnated. That moisture is not inimical to the setting naturally of any of the order Rosaceæ may be inferred from so many having their parts exposed directly upwards as if to receive descending moisture—rain or dew. At the same time we cannot but admit water driven against the under surfaces of the leaves to be diametrically opposed to nature. It is not, therefore, so foreign to nature to syringe a Peach when it is in blossom as to force water twice every day against the under side of its leaves after the fruit is swelling. It is done, of course, to prevent red spider obtaining a footing—a hold that it will not let go until driven by a force it cannot resist.

After the blossoms are set I am not in a hurry to resort to syringing the trees, but wait until the fruit commences swelling and has attained the size of a horse bean. The house is nevertheless kept sprinkled with water twice daily, the evaporating troughs never empty; and I would not even then resort to driving water against the under side of the leaves had not experience taught that it must be done if the leaves are to be kept free from red spider. The syringing twice daily is resorted to after the fruit is fairly swelling, and is continued daily until ripening commences, and the house is then damped twice a-day, and the evaporating troughs are not allowed to be dry so long as artificial heat is applied.

A good syringing is given the trees after the fruit is gathered, and is continued every evening so as to thoroughly subdue the red spider; for upon continuing the foliage in a healthy state until the wood is completely ripe depends future crops. If there is no red spider there is no need of the syringes. In respect of the temperature of the water for syringing I have a preference for it of the same temperature as that of the house, but am only particular in this matter whilst the fruit is young, having often given a thorough downpour over the trees as well as against their under surfaces with water from a hose-pipe as much as 20° below the temperature of the house without experiencing any evil consequences. I do not, however, recommend the water used for syringing to be lower in temperature than that of the house.

VENTILATION.—When the first blossoms expand an opening of about half to three-quarters of an inch is given the whole length of the house at top constantly day and night whatever the weather may be, and as the whole of the front lights open and do not fit very closely, so that even when they are closed air will pass in in proportion to that escaping by the upper opening. This increase of air is regulated by the temperature, as has been previously alluded to. I do not agree with raising the temperature artificially for the mere purpose of admitting air in large volumes—that, in my opinion, being tantamount to "doing evil that good may come." All that is intended by ventilation is the prevention of a stagnant atmosphere on the one hand, and preventing the temperature rising too high on the other.

DISBUDDING.—This is resorted to, to prevent overcrowding and to give shoots at required positions, as well as to secure the extension of the trees; also to secure suitable growths for the support of the fruit, and to provide for producing future crops. If the trees are vigorous they will be ready for disbudding by the time the flowering is past. Some advocate pinching out the points of the shoots which have fruit at their base, and most growers agree that disbudding should be done gradually, removing part of the superfluous growths at one time and part at another. Any who are timid over disbudding will have many useless growths, which must afterwards be stopped or cut out. I cannot see the value of allowing shoots to grow which must be ultimately removed. I can understand the necessity of not disbudding all at once when the trees are against walls or in a cold house, where the foliage acts as protection to the setting fruit, and its removal in quantity at an early stage may cause the leaves to suffer severely from blight, an evil which I consider is entirely due to insufficient protection. I have never had a "blighted" leaf in a heated structure, and in such a house I do all the disbudding at once.

When the shoots are long enough to be handled I remove unflinchingly every shoot or bud not wanted. I practise the long-pruning system, though I do not find fault with short-pruning, but have a decided objection to the finger and thumb being ever kept at work upon Peach trees—a certain mode, as I have found it, of having lots of blossom, the fruit also setting freely enough, but much of it dropping very soon from an insufficiency of foliage and sap. Presuming that the trees are fan-trained, the main branches 9 inches to 12 inches distance apart, and the shoots upon them 12 to 15 inches distance and trained in between those branches, we have to remove the shoots on the under and upper side of the branches, and leave side shoots for training-in at 12 inches apart, and at about every 3 feet a shoot will require to be laid-in and trained so that it will be at a distance of 12 inches from the shoot it originated from. A shoot will also require to be left for the continuation of each main branch. The bearing shoots have all the shoots removed except one at the base, selecting the lowest in every case for retaining, and one at the extremity of the shoot or above the fruit; and this shoot, not being required for extension, is stopped to three leaves, and any growth it may make afterwards is closely stopped at one leaf. Any fruiting side shoots failing to set are cut away to the lowest bud of their origin for the production of fruiting shoots for next year.

The shoots trained in from the base of the current fruiting shoots are, if very vigorous, stopped at a foot in length; but any shoots not likely to exceed 14 inches in length are not interfered with, as the moderately vigorous shoots of from 9 inches to a foot in length are always the most fruitful. One of the main objects to be aimed at is the equalisation of the vigour of the trees. It is better to cut away an over-vigorous shoot or restrain it by close pinching than permit it to monopolise nutriment needed by other parts of the tree.

PRUNING.—When the fruit is gathered we cut away the shoots which have produced the fruit, others being provided to furnish the crop of the coming year. Exception must be made of shoots that are required for extension, forming as they do part of the principal branches; and if the trees have any long bare branches no time is so fitting for their removal as when the crop is gathered, for we thereby admit the maximum of light and air to the foliage of the parts left, and enhance the ripening of the wood. When the leaves have fallen the trees are untied, and the pruning completed by cutting the shoots back to 8 or 9 inches of their length, and to a triple bud, or at least a wood bud, and if these are only produced at their base and extremity the shoots are not shortened, but are left their full length. Shoots required for extension are shortened so as to maintain the tree's equilibrium, and any unripe growths are cut back to firm ripe wood.—G. ABBEY.

FORCING LILY OF THE VALLEY.

We have received from the Hon. and Rev. J. T. Boscawen some highly superior flowers of this popular plant, and fully equal to the best examples of continental growth. Accompanying the flowers was a letter from Mr. Boscawen, which is worthy of attention on account of the special stress which is laid on the carefully maturing the foliage after the flowers have been gathered. As a rule much injury is done to forced plants of various kinds by subjecting them to an unnatural system of treatment immediately after they have ceased flowering. It is only by fostering a perfect growth of

foliage that perfect flowers can follow, and there are no plants to which this applies more forcibly than to Lilies of the Valley. By adopting this principle Mr. Boscawen has produced flowers from plants which have been in the same pots for ten years, and if others will follow the plan of this skilled horticulturist they will have equally satisfactory results, and we doubt not will arrive at the same conclusion, that there is "no difference between continental and English-grown plants." The following is an extract from Mr. Boscawen's letter:—

"I send you some Lilies of the Valley that you may see that it is possible to grow them in England as good as those flowered from imported plants. Much nonsense has been written of late years about French and Dutch *versus* English plants. I believe there is no difference. The blossoms I send are from a pot of roots taken up four years ago from a bed at least one hundred years old. I had some much finer (but out of flower now) that have been in the same pots ten years. I find it the best plan to force every other year, but to place all the pots in March under glass, in order that the leaves may grow early, being protected. By this means I obtain leaves as well as flowers at Christmas."

SELECT HARDY WALL PLANTS.

SOME two or three months ago a correspondent asked for the names of some climbing plants suitable for covering a fence. More pressing matters caused this to be set aside for the moment, and I yet now hasten to give the requisite information while there is yet time for the planting to be well done.

Climbers for fences should consist in the main of those which partake of the evergreen type, in order to secure an agreeable and lively effect throughout the year; several distinct sorts should be mingled together for the sake of variety and for flowers at different seasons of the year. At the present moment we have *Jasminum nudiflorum* laden with its bright yellow flowers, and, although bare of foliage, yet the green-backed spray always presents a fresh and lively appearance. The winter-flowering *Honeysuckle* (*Lonicera fragrantissima*) is abundantly clothed with handsome foliage, and with a pair of its pretty white and fragrant flowers springing from the axil of every leaf. *Garrya elliptica*, an evergreen of very stent robust growth, is now highly attractive from the striking effect of its tufts of long catkins of flowers pendant from the tip of every shoot. A little later on we shall have the bright yellow flowers of *Fremontia californica*, with the pink, blue, and white of the *Ceanothus* and *Escallonia*. Very few shrubs are so striking as is *Ceanothus rigidus* when seen in the full spring beauty of its dense clusters of pale lavender-coloured flowers. *C. divaricatus* is also a spring-flowering variety. It is an evergreen of much more vigorous growth than *rigidus*, and has such handsome foliage that a prominent position ought always to be given it. I have two plants of it, both about 10 feet high, one on the south side of a building and the other facing the west; they are in perfect health, but neither of them bear many flowers, and I shall be glad to know if it proves more floriferous in other hands. *Ceanothus azureus*, a good old autumn-flowering sort, is a general favourite, its handsome blue flower spikes always attracting attention and being most useful for cutting. I have had more applicants for its name than for any other of an extensive collection of climbing plants. With mild weather it continues flowering very late, and its flowers have continued opening throughout the present winter.

Of the *Escallonias*, *macrantha* deservedly ranks first, the elegant dark-hued, evergreen, glossy foliage forming a charming foil to its bold flower spikes of a deep rich pink, which open into full beauty in spring and early summer. *E. Ingrami*, while closely resembling *macrantha*, is certainly inferior to it in the size and colour of both foliage and blossom; but I would not entirely discard *Ingrami*, for it continues much longer in flower than *macrantha*, and its light pink flowers are very pretty. The white-flowered variety, *E. pterocladon*, bears a profusion of charming white Hest-like flower spikes early in the year. It is wonderfully robust, and climbs almost as fast as *macrantha*.

The *Honeysuckles* (*Lonicera*) comprise much too important a section of this charming class of plants to be left out. The winter-flowering *L. fragrantissima* has already been noticed; next to it comes *L. flexuosa* and *L. brachypoda*, the first having dark-coloured foliage and flowers, and the other being of a lighter hue in both respects, otherwise they bear a close resemblance in freedom of growth, perfume, and abundance of

flowers. Both are especially valuable for the rapidity with which they cover a building and for their sub-evergreen habit. *L. grata* is valuable as an evergreen variety, growing freely and coming into flower about midsummer. It is a very distinct variety, as is also the scarlet-flowered *L. sempervirens*. Some confusion exists concerning the nomenclature of this genus. In the selection of four or five here given I have retained the names by which they are generally known. In this neighbourhood the common Woodbine—the most familiar form of Honeysuckle—abounds, the roadside hedges being often crested with thousands of its flower clusters, loading the air with their delicious perfume. Poets have sung the praises of the Woodbine, but gardeners do not appear to recognise its value. Not a woodland walk should be without it and that other poet's flower the Eglantine (*Rosa rugifolia*), with the lovely pink-flowered *Rosa canina*, that in the wild grace of its bold yet most delicate flower sprays surpasses our best efforts in the formal Rose garden.

This paper is not intended to be an exhaustive one, and I must rest content with adding that Berberidopsis corallina, with stout, handsome, and very dark evergreen foliage and drooping clusters of coral-red flowers, ought to have a place in every collection; that *Cotoneaster microphylla* is quite the best climber for a windy corner or any exposed situation, clothing the wall with a dense growth of deepest green, enriched throughout winter with rich-hued crimson berries; *C. Simonsii* climbing quite as fast, and being equally effective in its way with foliage and berries of a lighter hue—the effect of both is wonderfully neat and trim; that the white-flowered Jasmine, *J. officinale*, should always have a place; and that *Amelopsis Veitchii* and *A. heteracea*, *Berberis Darwinii* and *B. stenophylla*, *Chimonanthus fragrans*, *Bignonia radicans* major, lots of Roses, and a perfect host of Clematis, upon which I may dilate upon a future occasion, are all "jewels rich and rare." Whatever may be your decision about sorts, plant them so that the growth may intermingle—the deciduous with the evergreen, light flowers with dark, blue colours blending with pink and white, and you will thus add much to the charms of what is always charming, and to the grace of what is always graceful and lovely.—EDWARD LUCKHURST.

ROYAL HORTICULTURAL SOCIETY.

MARCH 7TH.

FRUIT COMMITTEE.—HENRY WEBB, Esq., V.P., in the chair. A Paper was read from Mr. D. P. Bell of Alnwick relative to the withdrawal of the certificate in connection with the name Clive House Seedling Grape; and it was decided to associate the name of Alnwick Seedling in connection with the certificate. Messrs. Riven & Son sent a dish of very fine St. Michael's Oranges, grown and ripened in their houses at Sawbridge-worth. They were fine in flavour; also Maltese Blood Oranges of delicious flavour; the White Orange, with pale flesh, was good in flavour; the Prata or Silver Orange was also very good. The Committee unanimously awarded a cultural commendation. Mr. Bennett of the Pabley Nurseries, Barnet, sent an excellent basket of Garibaldi Strawberry, which was awarded a cultural commendation.

FLORAL COMMITTEE.—H. Little, Esq., in the chair. The exhibition ("meeting" is an inadequate word) was arranged in the conservatory, and was both extensive and excellent. The nurserymen's collections merit prominent notice, but the pressure on our advertising columns precludes a detailed account of the several collections. The morning was cold, yet many choice tender plants were staged.

One of the most prominent plants exhibited was *Dendrobium Pierardii* from Mr. Selwood, gardener to the Duke of Westminster, Eaton Hall, Chester. The plant was in a basket, and had twenty-three pendulous stems, ranging from 3 to 5 feet 4 inches in length, and densely covered with delicate flowers. The largest number of flowers on one growth was eighty, the total number on the plant 1124. A silver-gilt medal was worthily awarded to Mr. Selwood for this splendid plant.

W. H. Michael, Esq. (Mr. Newman, gardener), Cholmeley Park, Highbury, exhibited a very rich group of Orchids, comprising twenty superior *Phalenopsis*, *Dendrobium litiflorum*, *thrysiiflorum*, and *crasinode* very fine; the strikingly spotted *Odonotletia Brocklehurstiana*, *Colax ingens*, and excellent *Odonotoglossum*. An exceedingly creditable collection of Orchids was also staged by Mr. Ollerhead, gardener to Sir Henry Peck, Bart., Wimbledon House. The plants numbered about forty, and every one was in admirable condition. Amongst them we noticed *Trichopilia suavis*, *Lycaste cruenta*, *Cattleya citrina* and *Trianae*, *Dendrobium Wardianum*, *litiflorum*, and others; *Dendrobium glumaceum*, *Odonotoglossum nebulosum* and

Alexandrae, *Phalenopsis*, &c. Silver medals were recommended for the collections. Mr. Roberts, gardener to W. Terry, Esq., Peterborough House, Fulham, also staged half a dozen capital plants; *Cymbidium oburnum* was very fine, and *Brasavola venosa*, *Vanda suavis*, and *Oncidium* were noticeable. A vote of thanks was awarded.

Mr. James, gardener to W. F. Wilson, Esq., Reifless, Isleworth, exhibited fifty *Cinerarias*, which for the vigour of plants, size, substance, and rich colours of the flowers, have rarely been equalled and never surpassed. The strain was highly commended by the Committee, and for two splendid varieties (*Mary*, and *Thomas Winter*) first-class certificates were voted.

The plants exhibited by Messrs. Veitch & Sons were numerous and rich. *Lelia Veitchii*, a cross between *Cattleya labiata* and *Lelia crispum*, was gorgeous by its mottled sepals and rich labellum; *Oncidium splendens* was very striking, as also were many other Orchids. *Marantis Masanganae* and *Soneris margaritacea superba* were prominent amongst the foliage plants; *Cephalotus follicularis* and *Darlingtonia californica* were curious. *Abutilon Darwinii tessellatum* was laden with flowers, although the plants were only a few inches high. Lilies, Cyclamens, and *Amaryllides* completed this fine group. First-class certificates were awarded to Messrs. Veitch for *Encyclus australis*, a striking and valuable Crinum-like plant; *Rhododendron Taylorii*, rose flowers, freely produced and charming; and *Dendrostaedia davalloides Youngii*, a stately Fern of robust growth; also to *Osmunda palustris*. A silver-gilt medal was recommended for the collection.

Mr. Turner, Slough, staged fine heavily-berried standards of *Aucuba japonica*, *Camellias*, and a new Carnation—*Rose Perfection*—most free-flowering variety, attractive and sweet, and received a vote of thanks. Mr. F. Pan & Son, Waltham Cross, exhibited out blooms of *Camellias* in a hundred varieties—a splendid display of superior flowers, for which a silver medal was recommended to be given. Mr. E. S. Williams staged a varied and effective group of ornamental-foliaged and flowering plants, and also flowers of great merit of three varieties of *Primula sinensis*, and a vote of thanks was awarded. A first-class certificate was also awarded to Mr. Williams for a hybrid *Azalea*—*Mrs. Carmichael*. Mr. Wills exhibited a large collection of miscellaneous plants artistically arranged, also six new *Dracaena*—*Rebecca*, *Terminalis alba*, *Gladstonei*, *Elizabethae*, *Salmonia*, and *Sidney*. These plants were in splendid condition, and fully sustain all the encomiums which have been previously bestowed on them. A first-class certificate was awarded to *Terminalis alba*, which is almost certain to become a popular "market plant," and be in large demand. Mr. Dean exhibited an attractive collection of *Primrose*, and received a vote of thanks. Messrs. Osborn & Sons, Fulham, staged a fine semi double scarlet *Azalea*, a fine form of *Cyclamen persicum*, and a white serrated Carnation named *Guelder Rose*—a fine flower, to which a first-class certificate was awarded.

Messrs. G. Paul & Son, Cheshunt, exhibited two *Roses*—*Fortune's Yellow*, a coppery salmon colour; and *Beauty of Glenwood*, which is not striped, nor cannot in any sense be regarded as novel. Its appearance in its present form is certainly disappointing. The Floral Committee decided that the two *Roses* exhibited were identical, and Mr. Paul has done a service to rosarians in placing the much-wanted *Rose* in its right position.

Sir T. Lawrence, Bart., Burford Lodge, Reading, was awarded a first-class certificate for *Dendrobium crasinode Barberianum*. A vote of thanks was awarded to Sir G. Macleay, Penderell Court, Bletchingley, for *Echmea glomerata* and *Marica erulea*, which were referred to the Scientific Committee. The thanks of the Committee were also voted to J. S. Tyerman, Esq., Tregony, Cornwall, for hardy cut flowers.

A collection of *Epacris* was exhibited from the Society's garden at Chelwick.

NATIONAL ROSE SOCIETY.

The schedule has been now issued, and a most tempting one it is to all lovers of the Rose, whether exhibitors or simply growers of the queen of flowers, for such a schedule is sure to bring together a grand collection. £250 and more in prize, including a challenge cup of fifty guineas for amateurs, a five-guineas cup given by the *Journal of Horticulture* for the best twelve blooms exhibited by amateurs, and a five-guineas cup by Edward Mawley, Esq., for twelve Teas. The challenge cup is given by Messrs. Cranston & Co. of Hereford, and with the very liberal condition that it must be won in three years, not run over for an indefinite time—thus, if A wins it in 1877 and B in 1878, only A and B can compete for it in 1879. Already upwards of £130 has been given as donations, and upwards of a hundred members have enrolled themselves. The Committee confidently hope to increase the donation list until it covers the prize list, and to multiply their members very considerably

when the papers now ready for issue are circulated. The Horticultural Club has placed its room at their disposal, and all communications may be addressed to the Hon. Secretary, 3, Adelphi Terrace, W.C. All lovers of the Rose ought to patronise so laudable an effort as this to still further popularise the Rose.—D., Deal.

NOTES AND GLEANINGS.

THE EXHIBITION OF ARTIFICIAL FLOWERS AND FRUIT now being held in the central transept of the Crystal Palace, while containing several admirable examples of artistic skill, is the reverse of being imposing. The exhibits are arranged on half a dozen narrow tables, each about 20 feet in length, and a few dozens of plants in pots are placed on shelves at the front of the theatre. Artificial plant-making is evidently in its infancy, and we must candidly affirm that we were not prepared for such unnatural results. Nurserymen need not tremble in their shoes in this generation for fear of being superseded by the "artists." The wax plants are disappointing, and the fruit is far from being satisfying, even to look at. The Plums are decidedly the most natural in appearance, and some of the Pears, Peaches, and Nectarines are fairly well executed, but the Grapes are "dead failures." The greatest success is found amongst the flowers, some of which are truthfully, and it must be added dextrously, executed. Especially noteworthy is a group of Allamandas, Eucharises, Stephanotis, and Orchids from Mr. Charles Moggridge, 43, Charlotte Street, Bedford Square. A large and skillfully executed collection is also arranged by Mrs. Austin, Arnold Road, Tooting. Bouquets, especially those containing Rose buds, Camellias, and Bourdianas are attractive, but those containing Verbenas, Geraniums, and Fancies are less natural. Roses in several varieties, especially *Maréchal Niel*, are very true to life. Camellias are also good, the flowers being better than the foliage. A group of Water Lilies is very fine. A gigantic bouquet of mixed flowers commands attention by the richness of the colours and skillful execution. No flowers ever grew at all like them, but (perhaps in the artist's estimation) so much the worse for the flowers. Flowers in "gold and silver" are represented; also in wool, the latter being skillfully "worked;" but the most satisfactory display of the Exhibition is that of the skeletonised leaves, the delicate beauty of which commands much attention. Messrs. Dick Radcliffe & Co. contribute an attractive display of Grasses and Everlastings. The Exhibition remains open until the 17th. It is the first public display of its kind, and an inspection will afford pleasure to many fair admirers, especially if they do not go with "great expectations."

ONE of the finest DOUBLE PRIMULAS that has come under our notice is now flowering in the nursery of Messrs. E. G. Henderson & Sons, Pine Apple Place, Maida Vale. The flowers, which are nearly 2 inches in diameter, are produced in large whorls. In colour they are rosy carmine, and the petals are slightly serrated. This *Primula*, which is not yet in commerce, is named *Eva Fish*. It is not more remarkable for the size of the flowers than for the vigour of the plant, and must be regarded as a variety of the highest order of merit. Excellent varieties of these valuable plants also flowering in the same nursery are (*filicifolia*) Emperor, dark; (*filicifolia*) Empress, white; and *Magenta Queen*.

WE learn that the RUSSIAN SOCIETY OF GARDENING has appointed a special committee to prepare a scheme for the best mode of representing Russian gardening at the Paris Exhibition of 1878.

THE fourteenth annual exhibition of the LEEDS HORTICULTURAL SOCIETY is announced to be held on June 27th, 28th, and 29th. The schedule numbers sixty-eight classes, and liberal prizes are offered for plants, cut flowers, and fruit. The principal amounts are £24 for twelve stove and greenhouse plants, £20 for collections of plants grouped for effect, and £25 for show Pelargoniums. The railway companies will return plants, &c., from the Show free of charge provided they remain the property of the exhibitor. We have no doubt the Show will fully equal the excellent displays of past years.

WE have received the report of the EALING CURVANTHIUM SOCIETY and the schedule of the next show, to be held on November 10th. We are glad to notice that the Society is well supported, and the early issue of the schedule suggests also that it is wisely managed. The Right Hon. S. H. Walpole is the President, and Mr. Thomas Simpson, Audley Lodge, Florence Road, Ealing, the Hon. Secretary and Treasurer of the Society.

WE are pleased to learn that the MAIDSTONE GARDENERS' IMPROVEMENT ASSOCIATION is in a flourishing condition, new members, both honorary and ordinary, being enrolled at almost every meeting. A spring show is to be held on April 17th. No prizes are given; the members exhibit for the "love of the craft," and thus advance horticulture and honour themselves. The Association devotes a portion of its funds towards assisting deserving members during sickness or other causes of adversity. Such a Society deserves to prosper, and we cordially wish it success.

A CORRESPONDENT writing to us from the North Riding of Yorkshire on the late EVERE WEAHER and ITS EFFECTS ON VEGETATION, states that after all hope of filling the ice-house was past, the weather suddenly changed on the 26th ult., and frost set in with a fall of snow 2 inches deep, and on the three following nights, 15", 16", and 18" of frost were registered, giving ice 2 inches thick. Apricot blossoms are just showing colour, and Pears on the Quince are dangerously forward, those upon the Pear stock being later. There is a great promise of blossom of all kinds, and Roses had produced shoots 2 or 3 inches long which were quite killed; but the buds at the base of the shoots will, after being pruned in early April, the best time for pruning in a cold situation, grow strongly and afford good blooms.

A CORRESPONDENT who lives near the Bristol Channel writes:—"In reference to *Laurustinus* being late in blooming, it is true to a certain extent here this winter. We have many bushes; one of them was in flower in November, and it has been in bloom ever since. At that time others looked as if they would open their buds in a few days, and they are still no further advanced than they were three months ago. The weather has been very mild all the time. Should frost come in March (as I hope it will not) I intend watching to see if the cold will cause the flowers to open, and I may let you know the result. Would you say how many varieties of the white winter-flowering *Laurustinus* there are? There is a bush here which produces trusses and individual flowers three times the size of the sort commonly seen in gardens. As may be readily imagined it is vastly superior to it; in fact, the two will bear no comparison. Those who grow the *Laurustinus* for greenhouse decoration should obtain this fine variety." [There are half a dozen hardy evergreen *Laurustinus*s, the best being the one referred to by our correspondent—*Viburnum Tians lucidum*. It is valuable for garden and conservatory decoration, and is deserving of extended cultivation.]

MR. HAWKINS, gardener, Ewenny Abbey, Bridgend, Glamorganshire, tells us that he grew last year in pots Pitmaston Duchesse Pears weighing 27 ozs., Durandean 21 ozs., and Daynèe du Comice 17 and 18 ozs., that fruit being of excellent flavour. He wishes to know if other gardeners have obtained fruits as fine or finer.

IT is not generally known how valuable are the varieties of TREE PEONIES (*P. moutan*) for conservatory decoration during the early months of the year. At the Pine Apple Nursery these plants are grown and forced with great success. They flower quite freely in 5 and 6-inch pots, and their massive blooms in many hues produce a striking effect. The principal point to be attended to in forcing is to permit the flower buds to form in a cool temperature, and not until they are fairly prominent must the plants be placed in brisk heat. The named varieties of these Peonies are very beautiful, and their colour are never so clear and pure as when the flowers expand under glass. For general decorative purposes few plants can be more effective than those referred to, and of which more will probably be heard as their merits become better known.

THE DEER ROSE SOCIETY'S SHOW is announced to be held on July 17th. The schedule is a modest one. There are five classes for Roses, also classes for stove and greenhouse plants, and special prizes are offered for Pansies and table decorations.

WE are informed that the business of horticultural engineer and manufacturer of hot-water apparatus carried on so successfully by the late Mr. OMSON, at Stanley Bridge, Chelsea, will be carried on as heretofore under the same name.

IN the three winter months ending February the MEAN TEMPERATURE at the Royal Observatory, Greenwich, was 43.4°, and exceeded by 5.4° the average for the corresponding period in one hundred years.

THE Succulent house at Kew, which is at all times worthy of a visit, is perhaps specially so at the present time,

as containing a flowering specimen of AGAVE ELEMETIANA. The flowers are greenish-yellow, and the towering spike commands the attention of all visitors.

GLADIOLUS CULTURE.

MUCH has been written from time to time in the horticultural papers on the failure in the culture of the Gladiolus, and very recently in a contemporary on the (miasm) disease. It is an acknowledged fact that the Gladiolus is one of the greatest ornaments of the flower garden and one which commands the greatest amount of attraction at our autumn exhibitions. Many are deterred from growing this grand flower through reading these erroneous statements set forth by inexperienced growers.

Corms imported from France, as well as those grown in this country, have been submitted to our greatest physiologists for examination and opinion. A work also has been written by an able writer on horticulture on this subject, endeavouring to show that all the failures are caused by this contagious disease over which we have no control; yet no disease has been proved to exist. I have devoted a great portion of my life to the propagation and culture of this flower, and have no hesitation in asserting that no inherent or contagious disease exists, but it is a natural state of decay and exhaustion arising from age and excessive reproduction. Thus the truth of the old saying, "Pluck your flowers and save your plants;" the Gladiolus having a prolific tendency, producing, as it does, twice as much bloom as foliage. We do not experience more losses amongst the Gladiolus than we do among other bulbous plants; for instance, the Lily and Hyacinth, which are imported into this country in immense numbers; yet our gardeners are comparatively bare of these flowers. They do not die from disease; what, then, becomes of them? They simply die from exhaustion or wrong treatment. These as well as the Gladiolus can be grown in this country to as high a state of perfection as in any part of the world.

The method adopted here in cultivating the Gladiolus is very simple. The situation is an open field of six acres. The soil is sandy or gravelly loam on a bed of gravel. A moderate proportion of ordinary manure is used, and for those of the most delicate constitution I add a portion of peat and river sand. I commence planting about the 20th of February, and have now (March 1st) planted over an acre. The whole of the bulbs are planted in drills from 1 to 3 inches deep and from 2 to 12 inches apart, according to the size of the bulbs. Medium-size bulbs produce the finest flowers, although most purchasers prefer large-size bulbs, which accounts for so many failures, as many of these are exhausted from age and the strain put upon them the previous year.

The same remarks apply to the Hyacinth. Our best growers know well from experience that firm, solid, medium-sized bulbs produce the finest blooms. The bulbs are kept free from weeds and mulched over with short half-spent manure. All those in the store beds as soon as they commence blooming are cut and sent to all parts of England for decoration. Thus from the flowers being plucked in their early state exhaustion is prevented, and fine healthy bulbs are the result. In dry weather stimulants are resorted to by applying liquid manure, which I find beneficial.—JAMES KELWAY, *Gladioli Villa, Langport, Somerset.*

LIBONIA FLORIBUNDA—THYRSACANTHUS RUTILANS.

I HAVE presided over two most successful meetings of the Maidstone Gardeners' Improvement Association, to which several excellent specimens were brought to illustrate the discussions that were likely to arise.

I have never before seen of the Libonia floribunda such large specimens and so well flowered as those brought on two occasions by Mr. Longley, a gardener in the neighbourhood. He stated his plan to be, after flowering to ripen the wood well near the glass in a cool house; after that to cut the plant back in proportion to the growth it has made, and when started fairly potting firmly in rich loamy soil. Early in June the plants are plunged in the full sun and kept well watered, and twice a week with liquid manure of almost any kind; but he always mixes a handful or two of soot with it. I ought to say that he mixes rape dust with the soil and sand. He also brought a plant very little inferior to the one above spoken of that had been treated similarly up to June; but instead of

being kept in a pot it was planted-out and taken up in September and potted again, when it soon came into bloom, and will to all appearance continue so for some time yet. The effect of planting-out was to make the foliage larger and bring the flowers finer and also of a richer colour. The thanks of the meeting were awarded to Mr. Longley.

Mr. Cossem, gardener to Campbell Bannerman, Esq., M.P., produced a fine plant 3 feet high and proportionately large of *Thyrsacanthus rutilans*, which for fine foliage and its long racemes of large highly coloured flowers has not been surpassed at this Society's meetings. The difficulty in the cultivation of this plant is to keep its foliage in a healthy state, as it is known that a check will cause this plant to shed all its leaves, leaving its stems like so many sticks. Mr. Cossem uses peat and loam in equal parts, and plenty of sand mixed with the loam; but weak guano water is applied often, and the plant kept growing fast till flowering time comes.—T. RECORD.

ROYAL HORTICULTURAL SOCIETY.

So much space has been devoted to the discussion arising out of Mr. Wilson's guinea scheme that I am almost ashamed to ask for more, yet I must reply as briefly as possible to that gentleman's letter on 15th.

Mr. Wilson in parenthesis asks of me a plain question (he puts all his pertinent points in parenthesis)—namely, if I have asked "a single person to become a guinea subscriber?" Yes, I have asked several single persons and also many who are married to send in their names as guinea subscribers, and I know some of them have done so.

Next, Mr. Wilson objects to my conclusions that the results of his appeal are "impotent." We must judge of this in a comparative sense. I should be sorry to say that three hundred guinea subscribers to the Society were in themselves impotent; but when we consider that eighty thousand appeals have been generously distributed by Mr. Wilson, and that the gardening and daily press have given him such liberal aid; when we further consider that the term was only a quotation from Mr. Wilson's letter when he suggested the formation of a new society by those responding to the appeal; and when we find that the entire roll-call numbers less than four hundred guineaists, then I submit that the quotation of Mr. Wilson's term as applied to the efforts of the Council was perfectly justifiable. I thought, and hundreds thought, that from the high tone adopted that at least four thousand were ready to come in, and I could not resist expressing my disappointment.

Mr. Wilson at the first relied on numbers, but now these have proved so limited he takes refuge under names—"good names," "influential," &c., are mentioned. Granted that these are good and would be an acquisition to a royal society, still nothing can atone for the absence of numbers in a guinea scheme, the very essence of which consists in its numerical character.

I fully agree with Mr. Wilson that there are many hundreds of country residents who cannot be expected to contribute more than a guinea to the Society, and it is on this account that I am a believer in the guinea scheme, probably in the same sense as Mr. Veitch is (although I have not had an opportunity of consulting that gentleman)—that is, I am in favour of guinea subscribers joining the Society under present circumstances and as managed by a council which even on Mr. Wilson's own showing, as well as by other equally good proofs, has the confidence of horticulturists. Mr. Wilson's plan is to admit guinea subscribers only on the condition that the Society relinquishes the gardens at South Kensington—a condition which he knows it is impossible at present to carry out. Mr. Wilson also stipulates that guinea subscribers should have the full privileges of four-guinea or two-guinea subscribers—i.e., should have voting power. I once thought the same, but I am now satisfied that the request is untenable, and I repeat that if every guinea subscriber has a right to vote, everyone has a right to be a guinea subscriber; and on the same principle—the pretty theoretical principle—of equality, the distinction of privileges between the four and two-guinea members becomes an anomaly. I am in a position to know that that is the view taken by some large subscribers, and I am sure their opinions are worthy of consideration.

I am glad, however, to find that Mr. Wilson shows a disposition to yield his point relative to the severance of the Society from South Kensington, for he says on the page quoted, "If the [guinea] representative horticulturists would come in the Society would be leavened by the horticultural

element, which has been the great object of our work." Mr. Wilson further remarks—"Some would say the Society has still the South Kensington encumbrance; but if they were asked only for a guinea it is not they who would pay for this, they would get horticultural consideration for their guinea, while the £4 4s. and £2 2s. subscribers would pay for the South Kensington Gardens." Exactly. A more cogent argument could not be advanced in favour of guinea subscribers joining the Society as at present constituted, and Mr. Wilson can no longer (except on the matter of voting) object to their joining from this time henceforth.

I now revert to the question of voting. As a plea for the "approval of silence" given by Mr. Wilson and all the leading horticulturists to the policy of the Council (at the general meeting of the 13th ult.), your correspondent states that guinea membership was not mentioned in the report. That may be true, but it is equally true that the subject was prominently brought before the meeting and discussed, Lord Alfred Churchill clearly enunciating the policy of the Council, and to that policy, and at that proper time for doing so, not one dissentient voice was heard. A dissenion on a point considered by anyone to be vital could surely not be deemed "needless;" but in reality voting is generally esteemed as practically inapplicable to the great bulk of country subscribers; and although the term "voting" possesses an alluring sound, it is to those who would refuse paying a fine (travelling expenses) of, it may be, much more than an extra guinea to exercise it, only an alluring sound.

In conclusion I ask that as the Council is trusted as horticulturists desirous of doing the best for the Society and promoting the work it was established to foster, the guineas may come in, and I am not without hope that a horticulturist so earnest as Mr. Wilson will yet perceive that that is preferable to trusting to any casual "chapter of accidents."—A GUINEA MAN.

[As the plans of the Council are settled for the ensuing year, and as guinea members are now being admitted, we cannot occupy valuable space in the further discussion of a subject which can be of no practical benefit, and which has hitherto been productive of such feeble yet mischievous results.—EBS.]

FICUS PARCELLI FRUITING.

I HAVE a plant of *Ficus Parcelli* bearing a fruit. The Fig is precisely the same form as an ordinary Fig, but much smaller. I do not know if it will increase in size; it is now about as large as a blackbird's egg, beautifully variegated. Is its fruiting uncommon?—JUVENILE.

[This is the first time that we know of this Fig fruiting in England. As there are many to whom this beautiful variegated-leaved plant is not known we will add a few relative particulars. It is named after its discoverer, Mr. Parcels, plant collector for Messrs. Baptist & Son, Sydney. Messrs. Veitch and Sons were awarded for it a first-class certificate by the Royal Horticultural and Royal Botanic Societies in 1874. Its leaves are dark green profusely blotched with white.]

RED-LEADING SEEDS.

"D., Deal," says that notwithstanding having well red-leaded his Peas the mice have been at them. I wish to ask him if he prepared the seed in the manner I described, or did he fall into the same mistake which Mr. Fish laboured under when he recommended the seed to be damped with water instead of linseed oil? or are the Kentish mice of another species to those of a more northern climate? "D., Deal," does not state to what extent he has suffered, nor how many Peas he found stored up in his Auricula pit as a reserve for a future meal. I quite believe him in saying that he found some carried away. I myself, in the first or second year after discovery, on looking over the rows of Peas found five holes made by mice, and the following day the same number of Peas under a draining tile. What "D., Deal," has advanced does not prove the dressing of the seeds to be a failure, or that I am a deceiver. Such authorities as Mr. McEwen (see "Florist and Pomologist," 1875, p. 7) and Mr. Fish (see *Journal of Horticulture*, 1870, p. 396), with hundreds of practical horticulturists sustain me.

For the benefit of your subscribers I will just describe the proper way to prepare the ecde. Having a suitable vessel, say a tin can, large enough, shake the seeds round, adding by

degrees as much linseed oil as will give a slight coating whilst shaking, then add as much dry red lead as will make the seeds appear as if painted, and by well shaking in twenty-four hours they will be fit to handle. One teaspoonful of oil is sufficient for a quart of Peas, and for other seeds in proportion. I have found it necessary in the case of wrinkled Peas and Beans to use a larger quantity of oil, and allow it to drain off through a fine sieve. Seeds thus properly prepared I am certain, after the experience of more than twenty years, will be perfectly safe from the ravages of both rats, mice, and birds.—JOSEPH BURGESS, *Knutsford*.

PRUNING ROSES.

EVERYBODY is asking, How about pruning in this extraordinary season? I have been hoping to have seen remarks on the subject. You have many high authorities amongst your correspondents; but as private letters have been addressed to me, I will venture to express my opinion, in the hope of inducing others. It is this, that, taking one season with another, the first week in March for the south and south-east is as good a time as can be selected; and for Tea Roses at least a month later. Perhaps pruning may be desirable a week or two sooner on budded stocks which are to be cut back very close, and a week later will be desirable in cases where March "comes in" really "like a lion." Certainly, the difficulty this year with some excitable *Manettis* is to find a single bud anywhere to cut back to as dormant.—A. C., *Brockham*.

AURICULAS.

I AM sorry to see that our brother of Deal is among the afflicted with woolly aphid upon his Auricula roots; but when he speaks of having been utterly ignorant of its existence on this plant till recent notices of it in this Journal I am afraid he does not see the "Florist and Pomologist," in which so far back as last October I did what I could to put all growers on their guard against this secret foe. I spoke of it as "a terrible thing, infesting the roots, permeating the soil, starting apparently from centres of decayed vegetable matter in the compost, destroying the fine white fibres of the plant, and causing it to have a languid, dull, set look, very noticeable and distressing."

This intimation would, I thought, at least give each grower uneasiness enough to lead him to examine his own collection thoroughly to see that all was safe. Attention in the beginning of October would have made all the difference, for the plants in their autumnal growth would have rooted again before long.

The only counsel I have for my friend now is, that late as it looks, and forwarder as Auriculas must be in Kent than in North Yorkshire, I should still prefer ridding them of the pest to allowing them miserably to struggle through the bloom with this wretched insect preying on their vitals. The plants can only be even more and more distressed by leaving them in their present case.

Either they should be turned out of the pots and have their stems and roots well washed in soft soap and water, or at least the soil should have a good watering with that solution. I should prefer the former method, but should not now wash the foliage. It is so advanced that a Smiling Beauty or Glory would be quite ruined in appearance; and with "D., Deal," all the blooming foliage will be now developed, and all the rich meal would be lost by a leaf-bath.

Auricula fibres are in high activity now; and if they could even yet be set healthily to work in sweet new compost, I feel sure, from intimacy with these plants, the nature of which I have striven to understand, that to give them this chance is the best treatment "D., Deal," can afford them. That is what I should do, and I should have the new compost comfortably moist, so much so as both to work freely and yet support the plants without water for a week or more. I should keep them close for that time to encourage them to draw root, which Auriculas will always sooner do in an open soil than in one clogged and wet with water. When they showed signs of going along again I should give them air as usual, but they must be watched, and not allowed to become drawn. Hope, then, my friend will take heart again. It is no good doing nothing; therefore "why these weeps?" If he will tackle the enemy boldly and handle his ailing plants with such unremitting care as gentle Bob Cratchit had for poor Tiny Tim I can foresee that his nursing also will be rewarded and his afflicted plants recover, though they cannot of course recover

all their lost ground this time, and I hope that still his chances at the great south show may not turn out the ghostly thing he fears.

I am glad to know from a correspondent that Gishurst compound may be safely used to Auricula roots as a wash, though the plainer and effective remedy of soft soap contents me well. Still do I repeat the caution, Treat no valuable Auriculas with any lotion or medicaments of unknown powers and unproved effects. Try experiments first *in corpore villi*—on some cheap life, say of seedlings that are inferior and will be thrown away.

As to paraffin oil, a drop of it upon Auricula foliage I have found injurious. I lost a fine plant of Pizarro by one drop in the heart, but syringing plants with water just flavoured with it I have heard destroys green fly without hurt to the plant. If "D. Deal," wishes to experiment with it against woolly aphid on Auricula roots I should think it had better be very much diluted indeed, and tried first upon something of no value.—F. D. HORNER, *Kirkby Malzeard, Ripon.*

THE SEASON AND THE CALENDARS.

IN a season like the present, when the weather has been so inconsistent as to hinder the work and at the same time push vegetation so forward as to make it doubly necessary to have many of the routine operations completed early, it becomes a matter for immediate consideration as to what work there is a probability of finishing fairly well. I do not want to encourage laziness or unnecessary procrastination, but I would always have it borne in mind that "what is worth doing at all is worth doing well," and as it is quite impossible this spring to complete all which was contemplated, it is better to look the matter full in the face at once with a view to prevent attempting impossibilities, and to make sure that we do not get behind in everything, for if such a misfortune happens at the beginning of the year there is no remedy for it afterwards. If one were to read all the calendars of operations written for the present month and attempt to carry them out to the letter, there would certainly be an ignominious failure. There is so much which "must be pressed forward with the least possible delay," that there certainly would be no time to look round and think, and the harder one worked the greater would be the muddle and confusion.

No one can write a calendar of operations to suit everybody at every place and in every season. Calendars should only be taken as hints, and as such they are extremely useful, but generally speaking if followed to the letter they will do nearly as much harm as good, especially such as are written in standard books and intended to be used year after year. For instance: In Thompson's "Gardener's Assistant," the best book on practical gardening ever published, we read in the calendar for March that "the planting of deciduous trees should be completed as early as possible." Now, he who plants fruit trees in March this year will very likely have to plant again next autumn or the autumn following, and instead of gaining time he will lose one or two years besides his money and labour. Generally speaking there are only about seven weeks when it is proper to plant fruit trees—that is, from the last week in October to the middle of December, and instead of losing time everything will be gained by deferring planting all deciduous trees to next autumn, and properly preparing the ground during the summer.

There are generally two short seasons to plant evergreens: one is just as their buds are starting in the spring, in average seasons say the end of April, and the other towards the end of summer when the new growth has become a little hardened. Someone may ask, Why is it that evergreens may be moved so late in the spring, while it is forbidden to move deciduous trees at that time? The practical reason is that we know from experience, and the theoretic one that the old leaves of evergreens enable them to make roots quicker than deciduous trees could. Pruning of evergreens, if the health and vigour of the shrubs are studied, is best done late in summer after the growth is completed, say after the middle of August, and the only excuse for doing it in spring is that the stiff appearance left by cutting is sooner hid.

Turf may be laid at any time during summer with the greatest success. Where the ground has been newly made up or trenched I prefer laying the turf in summer or late in spring. Last summer was certainly sufficiently hot and dry to try the system, and it answered perfectly without one drop of artificial watering. The only precaution, and that was an abso-

lutely necessary one, was to cover the turf over with fine sandy soil to the depth of half an inch. The turf laid late last spring (the end of May), was carted two miles, laid rolled-up two or three weeks till it became blanched, and although laid on newly made-up ground was in perfect order for playing tennis on in September. The lawn could not have been used last autumn if the turf had been laid early, for the ground was of necessity prepared during the very changeable weather of winter, and consequently settled unevenly from the rains in spring.

Walks and roads are better made in summer than at any other time, but there is no harm in making them now if there is a lack of more important work; but work comes on apace at this time of the year, and some of it will not bear delaying a day.—WILLIAM TAYLOR.

AUTUMN-STRUCK CHRYSANTHEMUMS.

EARLY in December last I received seventy-five cuttings of Chrysanthemums in twenty-five varieties—i.e., three cuttings of each variety. Having procured some light leafy compost and a quantity of large 60-sized pots and drained them well, I filled them with the compost, and then made three deep insertions round the side of each with my finger, and filled up the holes with silver sand, inserting one cutting firmly into each of these little wells of sand. I thus had twenty-five pots, each containing one variety and taking up very little room. These I placed on coal ashes in a close frame, in a cold greenhouse in the full light, keeping them slightly damp and shading a little from bright sun.

Early in February they were rooted, and I have now potted off sixty-six healthy plants singly and placed them again on coal ashes in a cold frame out of doors, giving air abundantly. I have therefore only lost nine cuttings out of the seventy-five I originally had.—P. F. S.

WOOLLY APHIS AND THE AURICULA.

As the attack of the woolly aphid on Auricula roots does not seem to be widely known, and all information that can be collected is of value to resist an enemy, I offer a few more notes, hoping others who have had experience may do the same. Since detecting the enemy on my plants I have found it also on another and independent (since last potting) collection a few miles distant, but I observe no new features beyond the mere fact which call for remark.

In discussing such a subject it matters less how the pest came in, the remedies form the valuable subject for discussion. Experiments I have in hand since the potting season show it was not in the soil, of which I had five samples from as many different places. The manure, however, mixed in the proportion of one-third was uniform. But I imagine that an aphid—if indeed this insect be an aphid—passes some period of its existence in a winged state, and it seems impossible thoroughly to guard a free air-loving plant like an Auricula from the insidious visits of the full-legged aphid.

I am happy to say it has not taken as strong a hold of my collection as I at first feared; nevertheless, Mr. Horner's advice is so kindly given, and advice from so successful and experienced a grower is so valuable, that I should be ungrateful and unwise were I not to follow it out as fully as I can. In some cases I had already repotted and thoroughly washed my plants, roots and foliage, in a strong solution of soft soap and water, washing also the pot and throwing away the infected soil; while the frame in which they live is to be thoroughly washed and painted, and the woodwork laths on which the pots stand to be destroyed and fresh laths supplied.

I fear, however, that some plants are so forward that I must leave them and quarantine them till after the blooming. I have Col. Champeux, Lady Ann Wilbraham, Kay's Alexander, Meiklejohn, Conqueror of Europe, and some Alpines now in bloom; so it must be a question of quarantine for a short time till I can treat all alike.

I am very sorry I have given some plants away and exchanged others, and I cannot say how I regret the probability of having imparted the mischief to other growers. I have written to call their attention to the notice in the Journal, and this is all I can do.

I need scarcely say I shall not send any of my plants to any exhibition this year, nor allow them to leave my custody till I can conscientiously pass a clean bill of health. Adversity is the most instructive form of experience, and sorry as I am to injure my bloom for this year, extermination is the only cure

for an enemy which may itself be an exterminator.—JOHN T. D. LLEWELYN.

EXHIBITION PANSIES.—No. 3.

Of the older show flowers it is somewhat difficult to speak, their name being legion; but if I narrow the area of dissertation to the varieties I grow myself, and only refer to a few of the most meritorious, I may hope to succeed in not wearying your readers.

By common consent selfs are placed first in order, and following the rule I will refer to them first, though briefly. Of dark selfs those nearest perfection are free from shading and lack that shadowy blotch which so often surrounds the eye, though there are many very beautiful flowers which have not this distinction. Finale has stood its ground for many years, and is not likely to be ousted at present, and the same may be said of Locomotive, Robert Black, Alexander McNab, Rev. D. Taylor, and Miss Muir. The darkest I know is Erebus (Dicksons), and is an intense black of good substance; Count Biemarck, too, is black, but not by any means so good a flower as Erebus. Of good yellow selfs there is a large number, and selection is not easy. Cherub has long held its place as one of the finest, but its raiser (Mr. Henry Hooper of Bath) sent one out in 1875 which, though slightly deficient perhaps in quality, is a really good flower: I refer to Capt. Hayter, and it will be found to be very smooth, large, of the finest form, and with a splendid blotch. King Coffee came out with honours from Oxford, Manchester, and the Royal Botanic Society, but to my mind, of Mr. Hooper's two flowers, the Captain is the best. Golden Queen is a chaste light yellow of high merit, and Indian Yellow, Ophir, and Cloth of Gold are worthy of a place in the most select collections. The last-named has long been relegated to the ranks of bedders, but that does not cause it to be any the worse flower, and many inferior sorts even now pass muster at exhibitions. The best light self I know is Hooper's Duchess of Edinburgh, a beautiful cream with very large dark purple blotch, of exquisite form and wonderful substance. Cyril, though but of medium size, is a good flower, and George White, Helen Douglas, Marquis of Bute, Mrs. Turner, Mrs. Felton, and Royal Charter are admirable examples of this type. Though there are so many selfs and of so many hues, including black, white, cream, yellow, violet, purple, mauve, maroon, plum, blue, and mulberry, there is still room for improvement, and I hope that some day we may have a bright scarlet, rose, or crimson self to give additional attractiveness to exhibition pansies. The desired colours are already in some fancies, such as William Melville, rosy purple; Michael Scott, dark rosy red; George Wood, light crimson; Leith Walk Hero, carmine; and David Dickson, crimson, and we may reasonably hope that the busy bees or systematic hybridisation may produce selfs of the colours named.

Yellow grounds form a very large family, and there are so many of excellence that improvement seems scarcely possible. For a long time Robert Burns was the most esteemed, and not without cause, for its lemon ground and chocolate belt kept it distinct from its myriad purple-belted competitors. Defoe, too, held its place until Dickson's Christopher North discovered itself, and I may safely say a more handsome yellow ground I do not know. Walter McKay is an excellent flower, and William Catley (Hooper) is indispensable, being large, smooth, and constant. Beauty of Bath when ought is very beautiful, but with me it has proved as "fickle as fair." Amongst other good varieties John Downie, Miss L. Murray, Dr. Wood, Acme, Atlas, Senator, Sparkler, Perfection, and William Campbell are very distinct, and fulfil in addition all the requirements of good flowers. The kinds I have mentioned are for the most part constant, and this is a strong recommendation in Pansies. Last year I raised a seedling with a bright yellow ground and a broad brown belting, of medium size, perfect form, and good substance, but as inconsistent as a flower could possibly be. Now and then it came true, but sometimes the belting came in spots, and sometimes there was no belting at all. Of course under these circumstances it was worthless, but I shall try it again; and if I can persuade it to be true, an excellent flower of wonderful distinctness will be added to the list of yellow grounds.

Really good white grounds are scarce, though the number of kinds grown is great. Usually there is some irregularity in the belting, which, though apparently trivial, is to the florist an eyesore. In one the field is not well defined, the belting on the lower petal intruding upon the line laid down by the

side petals, and in others want of constancy is the leading fault, especially if the belting is a narrow one. Jane Grieve is the best variety I have grown, and is, as it claims to be, the finest flower in its class. I have never seen a deficient bloom, and, unlike many, it is a good grower, though not a profuse bloomer. Mrs. Galloway is a good flower with a deep bluish purple belting, and close up is the Medc with a broad purple belt. Dawn of Day, too, has no mean claim, its narrow bright purple belt rendering it very distinct and valuable. Mrs. Harbath, Miss Addison, Miss Bossey McAslan, Ladyburn Rival, Patroness, Bonny Jean, Mrs. Wrigley, Lady Paley, Mrs. Eyles, Mary Harper, and Tickler have merit, and are more or less to be depended upon. I have found that of all Pansies white grounds are the shyest bloomers, and last year this was especially the case, though, perhaps, the dryness of the season may have been the cause. Next week I will conclude my remarks with a few practical observations on cultivating and exhibiting.—M. H. MILLER, *Leck*.

As a florist's flower how little we see or hear of the Pansy—a flower that deserves to be more widely known and to be more largely loved. What can be more beautiful than the black velvety texture of Dux, or of the rich yellow of Golden Emperor? to say nothing of Alma, Princess Beatrice, Midland Beauty, John Currie, and other light and yellow grounds. I am not much in favour of fancies except as bedding Pansies. They are very pretty and afford a contrast to the solid colours of the more beautiful show Pansies. No doubt, as your correspondent has said in his article on page 98, that the Pansy has been a neglected flower, yet in our district it is never omitted from the schedules of flower shows. We have here Pansy enthusiasts, and I know men who have spent years of toil in cultivating their favourite flower.

I am glad that your correspondent admits having had a narrow escape of disqualification at the Nottingham Show. If he had been exhibiting at one of our local shows, where the Pansy is appreciated, he would have been—not almost, but altogether disqualified. I, with many others, went to that Show to see the Pansies and Roses, expecting to have seen the first prize for Pansies awarded to a pan worthy of the honour, and not to a mixed lot. The best pan of Pansies, exhibited by Mr. Taywell of Nottingham, was passed by altogether. I could have understood the award had the blooms been either all fancy or all show Pansies, but awarding the first to a mixed collection was past my comprehension. I find your correspondent considers that a pan has not that distinctness in a twelve show pan as in a mixed lot. I contend that a good Pansy judge can see a distinction in show Pansies without the aid of Belgian fancies; if not, then either the judges or the Pansies are at fault. Then, again, he says that in the catalogues of florist's flowers you see fancies introduced. I would ask him if he finds them mixed or whether they are separate? Every florist knows that there is a wide difference between a fancy and other varieties. What would be the result, for instance, if a stand of forty-eight Dahlias was composed partly of fancy and partly of show kinds, and another stand was wholly composed of show varieties? The answer is obvious.

I should like for all Pansy fanciers to read the characteristics of a good Pansy as described in "Florist's Flowers," sent out from the office of your journal, and they will there find what constitutes a good flower. I will quote the last characteristic, No. 7, as some of your many readers may not have seen it:—"Ragged or notched edges, crumpled petals, indentures on the petal, indistinct markings or pencillings, and flushed or run colours are great blemishes; but if a bloom has one ground colour to the lower petal and another colour to the side ones, or if it has two shades of ground colour at all, it is not a show flower; the yellow within the eye is not considered ground colour." That is what constitutes a good Pansy, and not the same as some your correspondent exhibited at Nottingham.—C. R., *Notts*.

PETUNIAS AND THEIR CULTURE.

THE Petunia and Tobacco do not at the first glance appear to be relatives, yet Petunia and Nicotiana are genera placed in the same natural order—Nightshades (Solanaceae). The very name, indeed, of Petunia is derived from the Brazilian name for Tobacco (*petun*), hence lovers of the "weed" should have a certain amount of respect for Petunias apart from their intrinsic beauty.

In very few plants has the improvement been so great and so

rapid as in *Petunias*, and it is a question if they are cultivated so extensively as their merits deserve, either as decorative plants for the flower garden or as specimen plants for the conservatory. Only a very few years ago the large flabby single purple *Petunia phœnicea*, and a flimsy-petalled dirty white flower (*P. nyctaginiflora*) were the sole representatives of bedding *Petunias*, but from these two species varieties increased rapidly after the ardent and indefatigable Donald Beaton first "broke the ice."

P. phœnicea was the first plant that Mr. Beaton took in hand for the purpose of solving a botanical problem and determining to what genus the plant really belonged. At that time doctors

differed on the point; one regarding the plant as a *Salpiglossis*, another a *Nierembergia*, and a third a *Nicotiana*. But with none of the representatives of these genera could the experimentalist obtain a cross, while with the old *Petunia nyctaginiflora* the typical purple *Petunia* crossed most readily, and the true genus of the plant was determined. New varieties now increased apace, *Shrubland White* and *Shrubland Rose* proving lastingly useful for bedding purposes; and it is a question if the latter has ever been (in its colour) superseded for massing, although *Countess of Ellesmere* is deeper in colour, and both come tolerably true from seed.

About twenty years ago a little "stir" was made in the

Fig. 23.—DOUBLE FIMBRIATED PETUNIA.

horticultural world by the announcement of a double white *Petunia* (*Imperialis*), sent out, I believe, by Mr. E. G. Henderson. This was expected to prove a valuable bedding plant, a character which it failed to attain; but it was largely cultivated for conservatory decoration. Other double varieties now followed in rapid succession, and a batch of English-raised seedlings (by Mr. Scott), which flowered in Mr. Beaton's experimental garden at Surbiton in 1858, were designated by their owner as the "royal family of bedding plants," from the fact that the varieties were named after the different members of the Royal Family, and had the high honour of a special visit from the Queen, Prince Albert, and the whole of the royal children, who called on Mr. Beaton at his house at Surbiton to see the new plants. That was sufficient to render *Petunias* fashionable, and there was "quite a rage" for them at the time, the rage—as rages often do—ultimately subsiding, and *Petunias* again fell into abeyance.

Petunias, however, have always been more or less cultivated, although they have been for a length of time quite overshadowed by the ever-increasingly popular *Geraniums*. The

Geranium fever, in turn, appears now to have reached its height, and *Petunias* once more have an increased measure of attention accorded to them; and well are they worthy of that attention, for few plants are more beautiful—bold without being gaudy, delicately perfumed, and easily cultivated.

A great advantage pertaining to *Petunias* is that they are readily raised from seed, and flower profusely when treated as half-hardy annuals. Double as well as single varieties are grown in this manner; the seed of the former being saved from semi-double flowers (the same as *Balsams*), and from this seed a certain number of plants are raised with flowers as double as *Camellias*—some with smooth petals, some serrated, some margined with a second colour, others veined, and the rest selfs. These are not adapted for bedding, but they are admirable for greenhouse and conservatory decoration during the summer months. They can, of course, be also increased by cuttings, and the best varieties should be thus perpetuated, at least until they are superseded by improved forms.

One of the finest collections of *Petunias* which I have seen is possessed by Mr. Cannell at Swanley, to whom I am in-

debted for the accompanying illustration of a seedling fringed variety, which shows the effectiveness of this type of flowers. Half a dozen superior named double varieties are Beauty of Clapham, white veined with pink; Snowball, white; Diamond, white suffused with pink; Patroones, white flaked and mottled with purple; Prince of Wales, white and violet; and King of Crimson, a fine rich self.

But the singles are as valuable as the doubles for cultivation in pots, while for bedding, especially in light soils and sunny positions, they are invaluable. For producing a rich dark bed, purple shaded with crimson, few plants can surpass Spiffire. Magnificent beds of this Petunia were produced at the Crystal Palace a few years ago. Shrubland Rose, as before mentioned, makes a pleasing mass of a distinct colour. But perhaps the most striking effect is produced by planting large masses of the margined and veined varieties in mixture—plants raised from seed. The "latest improvements" of these striped and marbled Petunias are very decided, and those who have not grown them have a treat in store.

The seed requires to be sown in pans at the present time and placed in gentle heat until the seedlings appear. The plants should then be placed near the glass in a light house or frame, having a temperature of 50° to 55°, and then be pricked-off in boxes or small pots to become established, subsequently to be removed to cold frames to harden preparatory to being planted out.

The soil should be light and rich, and should be well watered before the seed is sown. It should be sown thinly, very thinly, and be covered slightly and shaded until it germinates. Petunia seed is almost invariably sown too thickly, and the seedlings are retained too long in a high temperature before being transplanted, and a weakly growth is consequently fostered. Thin sowing, light air, and a genial temperature are the essentials for producing sturdy growth and satisfactory plants.

Plants raised from cuttings require much the same treatment, in fact precisely the same after roots are emitted; until then brick heat and shade are necessary.

The cultivation of plants in pots is very simple. Sound loam enriched with decayed manure, and rendered porous if necessary by an admixture of sand, will grow the plants admirably. They must not be overpotted, for Petunias are rather tender-rooted plants. Neither must they become pot-bound before being transferred to larger pots until the blooming pots are given. Attractive plants may be grown in 5 and 6-inch pots, 8-inch pots being large enough for specimens 3 feet in diameter. The plants cannot endure shade or a close atmosphere—"coddling" is fatal to success. They must have the lightest position at command, and abundance of air. They must be stopped frequently, not bruising the tips by roughly pinching, but cutting off their tops with a sharp knife. The habit of Petunias being naturally loose and straggling, stopping, tying-down, and training are operations which must not be neglected. Stopping may be continued until within six weeks of the time when the plants are required to commence expanding their flowers. When flowering manure water is necessary, and insects must be prevented by occasional fumigations.

Some of the newest named varieties are particularly attractive. Dr. Hogg has been justly compared to a Gloxinia, it is very distinct. Hon. A. L. Melville, Mr. Tillery, Mrs. Wright, Mrs. Shirley Hibberd, Miss Harrison, Captain Thomas, and Mrs. Wynne are striped and marbled in the most artistic manner, and if they prove constant will be very valuable for decorative purposes. It is only fair to say, however, that striped Petunias are sportive in their nature, and time is required to establish their permanency.—W.

ALPINE AURICULAS.

A SHADED body colour and deep yellow paste have hitherto been considered, in the north particularly, as the indispensable characteristics of a good Alpine. This year, I understand, flowers wanting in these points are to be permitted to be shown. It is not probable, however, that the discussion will drop altogether, and a few words on the subject may be opportune.

And first as to shaded colour. Among show selfs both shaded and non-shaded flowers are allowed; Martin's Miss Martin being an example of the former. It seems, therefore, unreasonable not to allow an equal diversity in Alpines—which of the two is preferable is a mere matter of individual taste.

As to white pastes, I object to them, not because they are

white, but for the reverse reason—because they are never purely white. They come out of a dirty colour, and bleach by degrees. Where the body colour is dark and rich as in Diamond the bright yellow paste is charming; but I have never seen this paste in flowers like Conspicua with violet tints. Bright yellow would not harmonise with these, and Nature, who paints with an inimitable pencil, accords to them (so far as I have seen) a custard-coloured paste. We must therefore either accept this or discard Violets altogether. The dirty white I have noticed above seems to arise from crossing the Alpine with a show self.—G. SPARKES.

NOTES ON VILLA AND SUBURBAN GARDENING.

RITCHIEN GARDEN.

It is noteworthy that the last half of this month and the first half of April is as busy a time as any in the year both for gardeners and amateurs. After arriving at the middle of March it is advisable to sow and plant as many crops as possible—that is, as soon as the ground is workable on the surface. Very little chance, however, has presented itself yet for seed-sowing, but all should be in readiness; and it may be that, owing to the wet, the soil will not work down well. We had last week two nights of frost, one of 8° and the next 11°, and if it had continued for a few more nights, though not so severe, much good would have been done to the soil. Wet days have succeeded the frost, and the soil is now worse than before.

The crops of Onions and Parsnips should be sown, also further sowings of Peas and Broad Beans should be made as soon as possible. A border must be prepared for several small seeds, such as those of Brussels Sprouts, Cauliflowers, Lettuce, Cabbages, Early Ulm Savoy, and Radishes. Turnips should always be sown in small patches until the middle of summer, as in garden ground they soon become hot and stringy. Asparagus beds should be made if any are needed, and the work should be done well, especially if they are to remain as permanent beds. The roots may be planted just as growth commences, and be covered over thickly at first, but to have a top-dressing of manure as they grow. Plant Horseradish if needed: it is not well to let a bed remain too long, or many small crowns are formed instead of large clean roots. Seakale, too, must be planted if a fresh plantation is required. Globe Artichokes must be attended to by removing all suckers which are not wanted, and levelling down the ridges of manure placed round the plants for protection, and digging it in between the rows. The suckers should be planted either to fill up the old bed or to make a new one. Now that the wheeling of manure is finished let the walks be put in order and have fresh gravel applied where necessary.

FRUIT GARDEN.

The trees are very forward. Apricots in the south have been in bloom some time, but where they have been protected by twigs of fir and laurel the frost has not injured them. One objection to the use of these is that in windy weather they blow to and fro and rub the blossom, or even knock it quite off. Hexagon netting fixed to the top of the wall, and pegged down at the bottom a little distance from the wall, is better than fir boughs. There is a very good show of bloom on most kinds of fruits, but particularly on trees which produced sparingly last year. Doyenné du Comice, Bergamotte Epereen, Easter Pear, Doyenné d'Etampes, Alford, Grosesne, Winter Neli, and Glout Morecan are prolific among Pears; and of Apples Lord Saffell, Stirling Castle, Cellini, Hawthornden, Searlet Nonpareil, Blenheim Orange, and several other sorts are very full of fruit buds. Plant early Melons as soon as possible; they need particular attention in the matters of heat and ventilation. There are numbers of sorts to choose from, and most of them good. In vinerias where the buds are breaking a little warmth must be given, and the temperature kept regular but by no means high for the present. Mr. Douglas, who is an excellent Grape-grower, narrates his treatment in such a practical way that if his weekly advice is followed few failures will occur.

FLOWER GARDEN.

Plants for the flower garden should be prepared as rapidly as possible. Geraniums which have been wintered in pots or boxes should now be potted singly in small pots, and be afforded a genial temperature until established, and then be removed to cold frames. Cuttings strike freely at this season if placed in heat and not shaded, but they do not flower so freely as autumn struck plants. It is only, therefore, advisable to propagate those more variegated sorts which are grown for the beauty of their foliage; and of these, plants raised in spring are equal if not superior to plants raised in autumn. Cuttings of Verbenas, Heliotropes, Ageratum, &c., require to be inserted in sandy soil, and be placed in a brisk moist heat and shaded until rooted. Plants of these, also of Petunias and Lobelias, may be raised from seed, sowing at the present time, so that the plants may have as long a period as possible to attain strength before "bedding-out time" arrives. Very useful is Verbena venosa, seed of

which should be sown at once by those requiring plants. The sowing of Stocks, Asters, Zinnias, &c., may be deferred, especially by those having limited farm conveniences for growing the plants. A bedding plant that deserves to be better known and more generally cultivated is *Leucophyton Browni*—a bright silvery-flowered plant with wiry stems, and growing about 4 inches high. It is excellent for carpet bedding, and is a tall plant among *Alternantheras*. I struck my plants last autumn with *Verbenas* on a spent dung bed, and now I have just potted them from the cutting pots. I shall grow them on as fast as possible in a close frame, and take cuttings from time to time and plant these out also. Pegging down is not needed if the plants are planted closely together and properly grown, but there will be a few shoots rise above the others, which must be cut off. As a dwarf-growing silvery-flowered plant it is worthy of a place in all flower gardens.—THOMAS RECORD.

DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

KITCHEN GARDEN.

As soon as the weather permits a sowing of Broad Beans and Peas will be made. For the largest-growing Beans the distance between the rows ought to be 3 feet, and for those of lesser growth 2 feet 6 inches. There are some who plant Savoys or Cabbage plants between the Bean rows, in which case they may be 4 or 5 feet apart. It is a good plan, especially in wet districts, to sow the Beans on turf placed in shallow boxes and plant them out after they are started. This system admits of a longer period in which to prepare the ground, but it is certain that they will not do well unless they are grown in a well-ventilated place and near the glass. The boxes should be placed out of doors for a few days before planting-out the Beans, which should be done in a careful manner, so that the roots may not be disturbed any more than is absolutely necessary. Peas may be treated lightly in the same manner as Beans. We generally sow the early sorts 3 feet apart, and late sorts 3 feet 6 inches. Peas which were raised under glass may be planted out either next week or the week following, according to their size and the state of the weather. If the soil is wet a little dry loam placed round the roots will be highly beneficial.

We have pricked out spring-sown Cauliflower plants, Early London and Walcheren. For our purpose a large quantity of plants is not required, hence we find it convenient to grow them in boxes; but when a large number must be raised the best plan is to prick out the plants on a prepared hotbed, not a steaming heat, but just warm enough to start them into free growth. They should be pricked out as soon as the seed leaves are fully developed, and after having grown a little air must be given, increasing it until they can bear almost full exposure, taking care, however, that growth is not materially checked during the preparing process. With us spring-sown Cauliflowers are ready for use from the middle to the end of June, those sown in autumn being ready about three weeks earlier. Another sowing should now be made on a warm border to succeed those sown under glass and brought on by its aid.

Parsley may be sown to form edgings for borders, and, if a good strain is obtained, the lively green beautifully cut leaves are very ornamental. When a very large supply is wanted sow in open ground in rows from 9 inches to a foot apart. No time ought to be lost in sowing Parsnips; if the ground requires manure it ought to be placed a foot below the surface, for if mixed with the soil the roots are very likely to be badly forked. We have planted out Spinach between the rows of Peas. We have planted out Onions from seeds sown in autumn. Our soil has a tendency to breed maggots, but the autumn-sown crop never suffers. We generally sow the White Spanish in autumn, and also a few in spring; but the best to keep are *James's Keeping* and *Brown Globe*. Onions are not yet sown, but they will be at once. We sow in drills a foot apart in preference to beds. As soon as the weather is fine and the ground is in good condition Carrots will also be sown in drills 1 foot apart. All small salads after this may be sown once a week, such as Cress, Radish, Rape, Mustard, &c. The kitchen garden ought now to be put into first-rate order; all the litter that has been used as protecting material during the winter should be removed, Celery trenches should be levelled, and any leaves that have been left on the ground should be carried to the rubbish heap. The gravel walks have been put in order by being relevelled. This was done two months ago; we would rather have done it this month, but it is not possible to crowd such work into March.

VINERIES.

Here we have plenty of work requiring the young growths into position. We have frequently said that the lateral growths should be stopped two leaves beyond the bunch. This is the rule, but in all vineries there are exceptions, sometimes owing to an occasional spur not starting, or a blank space occurring from any other cause; the laterals may be allowed to run to the third or fourth leaf beyond the bunch to fill-up the space.

On the other hand, if any part of the roof is likely to be overcrowded with leaves the growths may be stopped at one leaf from the bunch. When young rods are being trained-up to take the place of those which have become unsightly with long gnarled spurs, the leaves of the young rods should be well exposed to the light. It is certain that they cannot make good growth underneath the laterals of the old rod. Those who would grow first-class Grapes must not be afraid to thin-out the lateral growths; a good Grape can be produced when the Vines are a thicket of wood and foliage.

The Vines are in flower in the early houses, and increased vigilance is necessary to preserve them from injury. Cold cutting winds are apt, if allowed to blow direct on the bunches, to produce rust when the skin is tender. It is necessary to go over the bunches twice a day and gently shake them when in flower. Some gardeners lower the temperature of their vineries at the time the Vines are in flower and have been successful. We have generally raised it about 5° more than it was previously, and have found this plan to answer. Moisture is also withheld to a considerable extent.

Where Vines are grown in pots for the earliest crop they will now be in full growth and making roots freely. The roots must on no account suffer by want of water, and besides the surface dressing already directed to be given, every alternate watering ought to be with weak manure water to syringe, and it is considered objectionable to have sulphur formed into a paste by mixing it with soapy water. The pipes require to be heated to a considerable extent to maintain the requisite temperature for the remedy to be effectual.

Many growers are complaining that their earliest Vines are starting very irregularly, and this is not to be wondered at, especially where the roots have been under water. That was the position of our Vines, and it has only been by fixing powerful pumps, which are even now constantly kept at work, that the stakesholes have been kept free from water. The Muscats did not start well, but the reason was suspected, and the night temperature was kept down and they are now doing well. When it is ascertained that Vines will not break regularly they ought not to be pushed, as this only makes matters worse; lower the temperature to say 55°, and when the shoots have grown a little increase it to 65°.

FLOWER GARDEN AND SHRUBBERY.

By this time all alterations should be completed, such as forming new shrubbery borders, or releveling lawns by cutting the turf, and after making the ground level releveling it. This is a good time to prune the shrubs, especially *Portulac* and common Laurels. In our light soil, where the ground has been made rich by manuring, common Laurels grow with great vigour, but they do not last long in good condition unless they are periodically pruned; the under branches die and the plants are rendered unsightly, whereas if systematically pruned the bushes become regularly furnished with healthy branches. Large bushes which have been allowed to grow wild may be cut back to within a few feet of the ground, and they will start again into free growth from the old wood. *Portugal Laurels* may be treated in the same manner, but they do not run away into naked wood like the others; indeed, there are few more noble-looking objects to be seen in the pleasure grounds than large bushes of this shrub, and they may be seen in many places clothed with foliage from base to summit. If there is any planting still to be done it ought to be finished without any delay, and newly planted bushes should be mulched with manure. This is excellent for preventing evaporation and keeping the ground of a more equable temperature.

If lawns are poor now is a good time to dress them. An excellent dressing is wood ashes, guano, and fine soil in equal parts. A dressing applied now and in a month hence will cause a most vigorous growth. The fine weather has made the grass to grow very strongly, and we have rolled frequently and run the lawn mower over the grass twice. In a few weeks the walks will be relevelled or the old surface will be forked up, raked, and well rolled down again.

Although the Roses had made growths 2 or 3 inches in length we deferred pruning as late as possible owing to the danger to be feared from frosts. We had pruned half of them when frost did set in, Fahrenheit's thermometer registering on one occasion 11° of frost—quite enough to blacken all the growths on the unpruned plants. Frost suddenly disappeared on the evening of the 1st of March, and rather more than quarter of an inch of rain fell, when the pruning was finished; we then commenced to dig over the borders.

No time should now be lost in inserting cuttings of bedding plants that are likely to be required. Of many quick-growing plants cuttings struck in spring are more useful than those propagated in autumn. We shall shortly place the hardiest plants in a turf pit, which will give us more room for those which are being grown-on in warm houses.

FLORIST FLOWERS.

Tulips start very early into growth, and owing to so much

mild weather are in a forward state. They do not suffer from frost unless, as not unfrequently happens, water gathers in the axils of the leaves and freezes there. When the ground and leaves are quite dry they are safe. Auriculas are growing freely and require attention to ventilation. We found it necessary to double-mat the frames at night, and when the frost was most severe the leaves were even then crusted with it. Carnations and Picoetes have been potted into their blooming pots. Many growers pot their plants into 11-inch pots, three plants in a pot, or two in a 10-inch. Ours are mostly potted in 7, 8, and 9-inch pots. They are quite large enough to grow the plants; but there is this objection to them in the case of those who are away from their gardens in the daytime, the plants are more liable to suffer for want of water in hot weather. When large pots are used they do not suffer from this cause; moreover, there is sometimes not sufficient space for the layers in small pots. These plants require plenty of drainage, and the potting material should be good turfy loam with one barrowload of leaf soil and the same quantity of decayed manure to every five of the loam, a little slives and bone added if necessary. The plants require the protection of glass frames for a month longer at least.—J. DOUGLAS.

TRADE CATALOGUES RECEIVED.

James Carter & Co., 237 and 238, High Holborn, London.—*Illustrated Catalogue of Price Farm Seeds.*

Thomas S. Ware, Hale Farm Nurseries, Tottenham, London.—*Illustrated Catalogue of Hardy Perennials and Florists' Flowers.*

James Dickson & Sons, 108, Eastgate Street, Chester.—*Catalogue of Farm Seeds.*

TO CORRESPONDENTS.

All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

CYPRESS PLANT.—"E. P." asks for information in reference to the Cypress plant which grows in America. He has had some seeds given to him received from America, and wishes to know something of the habits and nature of the plant, and whether it will grow out of doors in this country or requires a greenhouse or stove. It has a pretty small flower. The chief attraction is in the leaf, which is beautifully coloured.

VINE LEAVES SPOTTED (L. D. E.).—We fail to perceive any spots on the foliage seen. There are some slight brown blotches which may be attributable to a sudden outbreak of sun after a period of dull weather. The leaves suggest although it is difficult to judge in their early stage that more yet judicious ventilation, and also a stimulant to the roots either in the form of manure or tepid manure water, would be advantageous for the purpose of improving the substance of the foliage, rendering it less liable to injury from changes of temperature or insect attacks.

LAWN SAND (Chemist).—We do not know of what it is composed. Any small mowing machine will cut the grass on banks.

GREENHOUSE RHODODENDRONS (A. E.).—The plants will not "throw" side branches until the terminal bud has become a flower bud, or the apex has removed. We have several plants which were growing up, years appear to be doing, with a single stem; we cut them down to 6 inches, and they are now furnished with shoots at that height. Cut them back to the height at which you require side shoots, taking care to notice whether they are grafted, in which case sufficient wood must be left, or the plants be cut to furnish fresh shoots. Keep rather dry until the plants begin growing again. They should be cut back at once. If you want the plants with stems of the present height of plants the removal of the central shoot or terminal bud will cause the formation of side shoots.

CUCUMBERS AND MELONS IN COLD FRAMES (F. I.).—The boxes you name are much too small, and are also needless, for there is no dirt arising from manure or soil that would injure the frame in the least, or only what could be washed off. It would cost less to line the frames inside with a deal board, half-inch thick and 11 inches broad, than to make boxes and a trellis. The half-inch boards would keep the sides of the frame clean. Put in the frames enough of the best manure, consisting of fine soil, 12 inches deep in the centre of the frame, diminishing gradually to 6 inches at the sides, and upon the dung place 6 inches depth of soil, and tread it very firm for the Melons, and moderately so for the Cucumbers. The soil should be a strong loam for the Melons, but medium-textured for the Cucumbers. The seed should be sown in gentle heat the first week in April, and the plants be potted singly in small pots when they show the rough leaf, and have their points pinched out when they have made two rough or second leaves, planting out in May. One plant in the centre of each light is sufficient. Telegraph is a good Cucumber, also Humpy and the variety of Telegraph, and Little Heath Melon will suit. Van Noitke Melon, scarlet flesh, is also a very good kind for cool treatment, and if you want a green flesh Easton Castle is good and free.

CLEMATISER AND TEA ROSES FOR LOW WALLS (Helm).—Clematis.—Mrs. G. M. France, Thomas Tonnent, Alexandra, Victoria, The Shah, and Madame Van Houtte. Tea-roseed Roses.—Duchess of Edinburgh, Gloire du Dijon

Catherine Mermet, Madame Level, Marie Steley, and Sombrell. We should have the Roses upon the west end of Clematis upon the east aspect. They would not do together. Passiflora coriacea succeeds against a south wall, and would probably thrive in your mild climate upon the east aspect.

PLANTING AMARYLLIS OUTDOORS (J. W. G.).—You may plant out all the species named—viz., A. atamisco, A. (Crinum species) longifolia, A. Belladonna, A. formosissima, A. lutea (Stenbergal), but the Asparagus should not be planted until May. There is no reason of frame, or to carry the glass, or it may be laid upon the soil over the bulbs until the growth appears above ground. There is no work of recent date treating of the cultivation of these plants.

SUCCESSIONAL CROPS OF MELONS (W. H.).—It is not desirable to have plants planted at intervals in the same house. Your house will only accommodate four plants, one under each light, and these we should plant at the same time, so as to have the fruit set, and ripening at about the same period. You will find some difficulty in growing plants in various stages in the same house and border; besides, four plants will not give you over a dozen fruit at a crop, and will not ripen off within a few days of each other. Easton Castle is a very fine successful bearer. Ormsanton Manor, with more flesh; A. F. Barron and Read's Scarlet-flesh are the best of that colour.

TACSONIA INSIGNIS BRIGHTER (T. E. D.).—The leaves do not appear to have been injured by cold. The appearance is that of an attack of red spider, of which there are traces upon the upper surface of the leaves, a result, probably of the plants having been kept too dry during the summer. We should prune the plants now or thin out the shoots, removing the worst affected leaves. The plants do little good in pots, requiring to be planted out, and are then grand.

PARAFFIN OIL (A. L. W.).—Paraffin, according to the testimony of Mr. Horner, is injurious to the foliage of Auriculas unless the oil is greatly diluted. Mr. Dickson of Arkelton and other gardeners have also found it injurious to fruit trees when used in its pure state. We have not yet tested its effect on seeds. We infer that the paraffin will do good, but we do not know how after the seeds are put in, and advise you to have the same. We have had no experience with eriolite acid, but would like to know who has.

CULTURE OF VIOLETS (M. J. D.).—Violets are so easily grown and require so very little attention that they are often neglected. They are propagated by runners, and to keep-up a supply of healthy free-flowering plants a few cuttings to be planted annually on rich sandy soil. Yours have not succeeded because "you did nothing to them last year."

PLUMS NOT BEARING (A. E.).—You may graft them as you propose. We fancy the Frogmore Damson is now to be had in the "trade," and that is the only way in which you can obtain it. Apply to Mr. C. Turner of Sloagh. The shading will do admirably either to protect the blossoms from frost cuts, or the fruit from flies and wasps in summer. You must not leave it over the blossoms during fine weather.

OLIVERAND UNHEALTHY (C. E. P.).—The leaves set are much infested with scale, especially on their under sides. You may adopt one of the following remedies:—1, Dissolve 4 ozs. of soft soap in a gallon of water, and with a sponge wash every leaf thoroughly, further displacing the scale by drawing a blunt pointed stick down the leaves next the midrib. Wash also the stems of the plant. The solution should be used as hot as the hand can endure it. The work must be well and carefully done. 2, Cut down the plant at any convenient height below the foliage, and it will shortly push fresh growth, and you will have a clean plant which will probably flower next year. We have often removed the paraffin with a little sawing in, and replace with fresh compost. If you do not cut down the plant give more copious supplies of water, and liquid manure once a week. It is impossible for your plant to thrive until it is freed from the scale and the dirty encrustation. We recommend sawing in a worse state, and we advise you to be prompt with either of the remedies suggested.

SWEED (C. L. Langley).—Taken literally "a Sweed" is a human being, a native of Sweden; but if the term was applied to this cultivated bulb, that bulb is Turnip. It is described in botanical works as a variety of the Turnip under the name of Brassica campestris rutabaga.

NAMES OF FRUITS (Connaught Subscriber).—Stamford Pippin.

NAMES OF PLANTS (C. Callan).—Probably Arum dracunculoides.

POULTRY, BEE, AND PIGEON CHRONICLE.

AN UNITED POULTRY CLUB.

Our article of last week was in type before the Aquarium Meeting, but at that Show we had an opportunity of talking with many experienced fanciers on the above subject. The impression seems to be that one united poultry club would answer all purposes better than any associations for particular branches. Very probably this would be the case, as a larger number of fanciers would most likely be thus collected together who could take all matters of dispute or interest into consideration. Such a club, however, wants to be delicately handled, and for it to be a real and permanent success there must not be a breath of antagonistic feeling among the members, for should they once cease to work in harmony the good derivable from any such collection of fanciers would certainly be frustrated. Consequently the club must be formed and put into working order as openly and as publicly as possible, when all could give their own ideas and so enable the rules to be drawn-up with the approbation of all. We mentioned twelve gentlemen last week which had been selected at random from a recent catalogue, and we see no reason why the same should not still be the leading parties to try and start this club. We know that several of that number have the subject much at heart, and talked the matter over at Westminster among themselves the other day, coming to the resolution that the thing was feasible, and that they would help the matter on. A general impression, however, seems to exist that the subject should not be pushed on in too

great a hurry, but that time should be given to collect the opinions of all interested in the matter.

We hear that a meeting for the purpose of forming such a club was held on the last day of the Aquarium meeting, and that certain resolutions were adopted and a gentleman chosen to act as Honorary Secretary *pro tem*. We cannot help much regretting, as do so many more, that this meeting did not take place on an earlier day in the Show week, for by Friday so many of the fancy who are interested in the matter had left for home again, and surely the more that could attend a meeting where a subject of such general importance was to be discussed would have been the better. Still the resolutions passed, we hear, are not to be made public until they have been before another meeting, and so those who were present on that first occasion have still ample time to consult the opinions of others who were not present; for we know several important breeders and fanciers who will never allow themselves to be "idden over roughshod," and so if this meeting, held the other week, is to be the nucleus of the United Poultry Club, perfect openness and no secrecy must be employed.

We have seen a letter in a contemporary written by some one who was present at this meeting, saying that it was his "privilege to receive an invitation." We confess this word "privilege" astounds us. If this meeting was for the private interests of particular persons we can imagine the writer considering it a privilege to join such a coterie; but when it was held to consider the wisdom of establishing a poultry club to embrace all real and loyal fanciers, surely at a first meeting for the purpose no publicity could have been too great nor no number of fanciers too large to carefully take into consideration such an important matter. We say openly and with certainty, that once the matter is conducted secretly and among certain parties only, the Club will do ten times more harm to the cause than ever it will do good.

From the general tone of the letter to which we have referred we should think that it was written with the full approbation of the gentlemen present at the said meeting, although no names are yet announced. Whether this is so or not, we still take this opportunity of most fully concurring with one paragraph—namely, "It was deemed essential for the prosperity of the Association that it be entirely unconnected with any journal published in the interests of the fancy." We assent most cordially, for we are sure that this is important. There are, we conclude, however, persons in existence who read daily a penny paper who do not read the *London Times*; but again there are fanciers who read our pages who read no others which are devoted to poultry culture; and so we agree with the correspondent of our contemporary, and say that, fatal as it would be to make one journal *facile princeps* the organ for ventilating the Club movements, still it would be as damnable to it not to allow all journals to fully recognise the movement, and by ventilating the subject and recording the movements to help to form, collect, cement together, and amalgamate fanciers of poultry and of Pigeons. It is unison that we want—the joining together, for one common purpose, of all fanciers; and only by the absence of petty jealousies, by shelving former disputes and quarrels, by working together in true harmony, will the poultry fancy in their Club succeed. Meet earnestly do we trust that this may be the case; and fairly, firmly, straightforwardly stated, we do believe a poultry club which properly considers all subjects laid before it, will work a real benefit in the poultry world.—W.

THE LIABILITY OF RAILWAY COMPANIES.

A CASE of considerable interest to poultry and Pigeon exhibitors was tried at the Bradford County Court on the 23rd ult., before Mr. Daniels, Q.C., in which Mr. Thresh of Bradford sued the Lancashire and Yorkshire Railway Company for £1, which he alleged he had lost by the neglect of the defendants. Mr. Terry appeared for the railway company, and Mr. Thresh conducted his own case. The plaintiff stated that on the 22nd of September last he sent a pen of Spanish fowls to Chadderton Agricultural Show, Moston station, by the Lancashire and Yorkshire line, at 9.10 P.M., but instead of the birds arriving in reasonable time they were delayed until 12.40 P.M. next day, when the judging was over. The plaintiff now claimed £1, the amount of the first prize, and he called Mr. Dixon the judge, who stated that if the birds had been in time he should certainly have awarded them the first prize. Mr. Terry, for the defendants, contended that the company had entered into no contract for the delivery of the birds at any specified time. Mr. Daniels ruled, however, that the defendants, by allowing the fowls to be booked to the show, had bound themselves to deliver them in reasonable time; otherwise it would have been needless sending them. He therefore gave a verdict for the plaintiff for the amount claimed with costs.

BOURNEMOUTH SHOW OF POULTRY, PIGEONS, AND CAGE BIRDS.
—The defaulting Show to which "WILTSHIRE RECTOR" referred

was quite a financial speculation on the part of Messrs. Barnes and Co. of Portsmouth; and being held before the Winter Garden Company was in existence, or rather before the Winter Garden was built, it could have no possible connection with it. The Dog, Cat, and Rabbit Show held by the Company in November last reflected great credit on the promoters, and all claims were settled within a short time; I believe to the satisfaction of the exhibitors generally.—GEORGE BULLETT.

THE PATAGONIAN RABBIT.

THE Patagonian Rabbit is the giant of the Rabbit tribe; towering above all the other breeds, it stands unsurpassed and unequalled for size and weight. A fine full-grown and fat specimen of this breed will outweigh three small Dutch Rabbits. At this period, when butchers are "piling on the agony" and even passing the shilling-per-pound price, surely everything that can with advantage be brought into the meat market should be, and what can be more advantageously introduced than the mammoth Rabbit species? The Patagonian is not a Rabbit that a lady or child would select as a pet, as it grows awkward in appearance—the larger, and hence more valuable, it becomes the less graceful it appears. Still appearances are often deceitful, and "beauty is only skin deep," so I think we are right if we affirm what is corroborated when we say that this is the most valuable breed of Rabbits extant.

The Patagonian is indigenous to France and Flanders, and probably never saw Patagonia. The only possible claim it can have to the name is its size, and even this cannot be advanced as a very cogent one. Its importation into this country has never been accompanied with much success, as Rabbit fanciers are such thorough-going conservatives that as long as the Lop is present for them to experiment upon they will not welcome a stranger. So the Patagonian has been nourished and cultivated by a few only, and their cultivation has not resulted in improving the breed much, as it is no better now than it was ten years ago, and foreign blood has been so freely introduced that the thorough-bred Patagonian is seldom seen in a rabbitry. In France, however, it is different. The present do not carry away many francs for their wares, and so, instead of grumbling and joining unions, they save what they can, rent a small piece of ground, and keep such animals on it as they can. If large, some of the larger and more valuable animals are kept; but if the land and resources are at once small Rabbits are taken to, and found to pay admirably. In this case Patagonians are almost always selected because of their great size, and because they eat but little more than their smaller brethren, and certainly require much less attention than their fastidious relatives the Lops.

Having briefly mentioned the nature of the breed as an article of commerce, we come next to its characteristics. The Patagonian should be as large as possible—large all round—that is, long and broad. Controversies on the size question are very fashionable among Rabbit keepers, but it is an admitted fact that size in a Patagonian is the great criterion. But this is not all. We must have something more besides size; we must have shape. The frame of the Patagonian should be roomy and bulky. The head should be large and bull-dog-like—that is, the face should be broad and the nose somewhat stumpy. When in condition the cheeks will swell out a good deal, presenting a heavy look from the front. The eye should be large and bold, and if it does not glow, sparkle, and look full, it is certain that the animal is in bad health. The ears should be very long and heavy. In a Lop length, thinness, and grace are the attributes of the ears of a good specimen, but with a Patagonian it is different; length, breadth, and thickness—or, to sum up in one word, massiveness—are required. I admit that in an animal reared for pot purposes the ears are not of vital import, but still as the type of breed they require attention. They must stand up from the forehead in an upright position, the muscles being strong enough to effect this. The ears, however, are too heavy (top-heavy is perhaps the correct word) to remain perfectly upright, so that they gradually drop outwards. Thus a person standing in front of a Rabbit of this breed can see between these organs with ease. The neck is generally short and heavy, and the shoulders are set wide apart. As a matter of course the legs are similarly placed. From the shoulders to the hips the sides gradually extend outwards, and the back rises. The hind legs are very long, and are set a considerable distance apart. They are also very thick and heavy. The whole formation and shape then, is heavy and massive.

The fur is very thick, and about the same length as the Lops, or perhaps a trifle shorter. The ears are covered with a profusion of hair on the outside, and on the inside are generally blackish, and not very pretty. The fur on the head is not so long as on the body, and generally of a softer quality.

The Patagonian presents neither beauty nor variety to the eye, but is of one regular colour—a dull heavy grey, or more correctly speaking, a very dark greyish brown. A wild Rabbit is generally called grey, but it is not really grey at all but

merely brown, of a more or less grayish shade. The Patagonian is much darker than the wild warren Rabbit. If a pencil be drawn up its back it will be seen that there are a large number of black hairs predominant, and these give a dark shade to the fur. The colour, then, of the breed under notice is dark grey, as it is orthodoxly called. The head is generally inclined to be a little darker than the body, and this is no detriment. The under parts are lighter, sometimes almost white, and although there should not be too much of it, a specimen will rarely be seen without it. There should not be any signs of sandiness either above or beneath, but the junction of the two colours should be light grey.

The points, then, are these:—Massive frame, with rump considerably larger than fore quarters; large head; large and semi-pendant ears; dark grey body and head, and light underparts. The light colour should not be discoverable, except upon examination. When in a reclining position the animal's sides gradually extend outwards, presenting from the front a form of a capital V.

The Patagonian is not very docile, but is not by any means aggressive. While not fond of caressing, it may yet be taught to know and recognise its feeder, and is moderately sociable. The doe is fairly prolific, though not so good in this respect as the smaller varieties. About three litters a year, and from three to five in each litter, may be confidently looked for.—GETA.

HEDGEHOGS.

THOUGH fully agreeing with "WILTSHIRE RECTOR" in his remarks respecting the preservation of and kindness to all dumb animals, I cannot quite endorse his statements, quoted from a French paper, as to the harmlessness of hedgehogs. I can bear witness to the fact that they are sad thieves of eggs, even climbing low shrubs to obtain the eggs of small birds, and also robbing partridge nests. Some years since our men were removing some timber; underneath the logs was a hedgehog's nest with several dozen eggshells in it of all kinds, and a litter of young hedgehogs about a month old. I have also had these animals so tame in the house that they came when whistled for, and the greatest treat they could have was a fresh-laid bantam egg. I have no doubt they, like all other animals, are most useful in their way, but, like the graceful squirrel, requires keeping within bounds.—AN OLD SUBSCRIBER.

THE CRYSTAL PALACE BIRD SHOW.

(Continued)

CANARIES and Males numbered considerably more than one-half of the entire Show, most of the principal breeders and exhibitors being represented with their best peppered and non-peppered birds. There was an immense competition in the first half-dozen classes (especially the "Clears") for the honors and extra £1 given to the highest winner in the Norwich peppered classes. Messrs. Mackley Bros. of Norwich were the victors. In the half-dozen classes there were 291 exhibits, averaging nearly fifty in each class. The other classes throughout the exhibition were well represented.

The principal prizetakers in Class 1 were Mr. John Adams of Coventry, whose famous champion Yellow (a bird full in size, and possessing colour, condition, and all essential qualifications for an A1 show bird) succeeded in winning first honours in its class at the best show ever held at the Palace. We assert this without the slightest reservation. This may be considered as one of the greatest victories in the Show, Mr. Adams's bird having to compete in its class with seventy-seven others, most of them really fine birds in the eyes of numerous observers as much like the others as the others were like them. Other noted exhibitors brought forward their high-coloured beauties, notably a couple belonging to Mr. R. J. Pope of Brighton, the lesser-priced bird of the two running Mr. Adams's top-sawyer a closer race than we have known any other Yellow bird to do during the past season, although Mr. Adams has had his bird placed second on more than one occasion. Mr. Pope, however, took a second and a third; Messrs. Cox & Griffin of the Northampton school splitting the pair for an extra second place, and keeping up the lusting reputation of the town noted for its high-beeled steppers. Mr. J. C. Salt of Burton with his very hot eight obtained an extra third position with No. 12, not his highest priced bird, which lacked thorough condition compared to numerous others in the class. Whether Mr. Salt's No. 10 (very highly commended) be the identical bird or not which gained him a first and extra prize at Reading Show a week or more previous, we are unable to say. Mr. G. E. Russell of Brierley Hill, Staffordshire, scored a clever fourth; Mr. Athersuch of Coventry fifth; and Mackley Bros. of Norwich an extra fifth. With so fine a lot of birds in the above class to dispose of for prizes, the task of awarding them must have brought into requisition much close attention, from the fact of an hour and a half fully being devoted to judging the Yellow.

In Class 2 an almost equally difficult task had to be encountered

over the sixty-six Buffs. The first prize was awarded to a most magnificent type of a Buff, full of bloom, quality, and in the very pink of condition; in fact a great bird of its variety, and one doing credit to Mr. Athersuch, who likewise gained an extra third and an extra fifth with other meritorious specimens. Mr. Galey of Clapham took a clever second and equal fourth; Mr. Russell an equal second; Mr. J. Caplin of Canterbury third; Mr. Yallop, Cossey, near Norwich, fourth; Mr. W. Havers, Norwich, fifth; and a similar degree of merit to Mackley Bros., which completed the list of prizewinners in the class. The competition in many instances was close, and the awards were doubled compared to the schedule.

The two "Clear" classes being disposed of, judging travelling became somewhat lighter, the classes were patiently gone through one by one. The "Even" and "Unevenly-marked" Yellows and Buffs were very showy; Mr. D. Audley of Leicester carrying off three firsts out of four classes, Messrs. Mackley and Athersuch being the next best winners.

The non-pepper-fed birds mustered well, and in most instances true in colour to the call of the classes. Mr. R. J. Troake's first Clear Yellow was very fine, and was well backed up with Mr. Pope's third, and Mackley Bros.' second and fourth, which latter exhibitors won first, second, and third in Class 8, Mr. Salt gaining Mr. Wallace's bird book for fourth honours. The first-prize bird in Class 9 certainly must have been a mistake, owing to the high pepper colour it presented. The Crested birds bore the usual, and we may say unusual, attractive markings and abundant crests, the chief winners being Mr. G. E. Russell of Darlington, Mackley Bros., and Mr. G. E. Russell.

As to the Belgians, they were not only high in their shoulders but high in their numbers, the chief winners being Mr. J. Doel of Plymouth, who scored a first (with immense shoulders) and equal third in Yellows and a second and extra third in Buffs. Mr. Rutter of Sunderland took no less than eight prizes in three classes—sufficient for any ordinary exhibitor, but insufficient for one of such extraordinary Belgian proclivities he possesses. Were Mr. Rutter permitted to get-up his own birds "against a wall," and not beneath the canvas tent provided, then perchance they would show to better advantage true Belgian form, which they failed doing owing to the queer ways they had (in several instances) of shooting out their tails and balancing their bodies upon their legs. We like to see a bird with good stand, small head, and sweeping neck, with close tail down to the perch, and hoisting up a well-filled pair of shoulders as high as it can get them. We much admired the general style of Messrs. Wright & Smethurst's second Yellow and first Buff.

Although there were twenty-eight entries in the two London Fancy classes, Messrs. J. & W. Waller of Finsbury, London, took the entire six prizes—not at all to be wondered at considering the style in which the birds were moulted and brought for exhibition. We know from experience that nothing is more difficult to achieve in Canary fancying than bringing out "London Fancy" birds in proper show trim.

We will continue our remarks next week.

AMERICAN APIARIES.

LIKE most things in America, bee-keeping is there commonly carried-on on a much larger scale than in England, and from the levithan honey-raiser, Mr. Harbison of California, with his three thousand hives, to the small bee-farmer owning but fifty or one hundred stocks, all use the frame hive, and more or less the extractor. The variety of patterns and dimensions of frame hives are endless; but the principle of all combs being moveable and frames interchangeable is fully recognised. I have before me a photograph, lithograph, and two woodcuts of different bee-garners, the first, where no exaggeration can be charged, to illustrate my present article. The spairy is that of Mr. A. I. Root of Medina, Ohio, well known as a bee-writer under the *non de plume* of "Novice," and editor of "Gleanings in Bee-culture," a monthly magazine wholly devoted to our hobby. Mr. Root is eminently an experimentalist—has tried all schemes of bee-keeping, most hives, engers, and feeding dodges; his manifold failures and successes all being duly chronicled in his Journal. It will be perceived that the hives all stand on the ground or nearly so, and this is the case in the other aparies as shown on the pictures I have. I should prefer some elevation both for comfort in working and for fear of damp; but perhaps their climate is drier than ours. Behind each row of hives is seen a trellis on which is trained grape vines, affording grateful shade to the bees and profit to the bee-master, as the Grapes in Ohio ripen readily thus cultivated.

The building in the centre of the picture is the bee-house, used both as a workshop and store. On the right of the house is a colony suspended by a spring balance, of which the daily loss or gain is noted, and which gives timely warning of a glut of honey when it occurs. In front to the left is seen the extractor, a busy machine here, for Mr. Root is one of its strongest advocates, although he has followed the times and lately gone in for sectional supers, of which he has kindly forwarded me some

neat and inexpensive patterns for our enlightenment. Mr. Root appreciates shade for his bees; but in most American apiaries the hives seem to be simply set down in open fields without any protection whatever.

Great attempts were made in the United States to institute a "standard frame," and there is one so-called; but the name is practically useless, for bee-keepers will use their own judgment as to the requirements of their bees and locality. The same question was discussed by the British Bee-keepers' Association for England, but recognised as impracticable, although I see

system of management. Throwing up such a cloud of theoretic dust may help to amuse Mr. Lowe; but has it not already blinded his ally—the patriarchal Mr. Pettigrew—to publicly disown "his sin true love," the big straw skep, and actually embrace at his champion's bidding the empty wooden boxes from the grocer's shop? To help to allay this dust I would put one or two questions.

Would Messrs. Lowe and Pettigrew kindly state the extent of their experience (if any) of this Stewarton hive and system of bee management? So far as the records of the apiarian comb

Fig. 24.—AMERICAN APIARY.

two hive-makers advertise their wares as the "standards." It may ease the minds of straw hivists here to know that the Yankees are too 'cute to go in for expensive hives. Most of their hives cost no more than \$2 or \$3, and frame hives in England need not cost more for profitable working; indeed, they may be had quite as cheap as Mr. Pettigrew's excellent large skeps, with their floor-boards, supers, and covers.—JOHN HUNTER, Eaton Rise, Ealing.

THE BATTLE OF THE HIVES.

IN this controversy we have already pointed out to Mr. Lowe it lies not between all hives and systems of bee management, but simply two—the Stewarton and the straw—for comparative honey results. We may, therefore, be pardoned if we ask the practical utility of all your correspondent's verbiage meanderings, this mere play on the meaning of words, this hive *qua* hive, this word-splitting attempt to sever the hive from its

show they have none. I would ask further if they have ever even seen a well-managed 46-inch octagon colony at work? May their position not be similar to my respected friend President Bennet, who had the frankness, as well as the generosity, to record in these pages that in my apiary the last summer "he had been introduced to a phase of apiculture of which he had previously no conception." Admit this till we are informed to the contrary, and does it not savour somewhat of presumption that either gentleman should pass judgment on what they have no experience whatever? But, says Mr. Lowe, look at our backers, Messrs. Abbott, Symington, "B. & W.," and all the authorities; only think, "Bevan, Golding, Dunbar, Jardine, Langstroth, Huish, and Taylor, and many others I could name." So far as the apiarian records show the first two gentlemen—Messrs. Abbott and Symington—have no experience of the Stewarton hive; and as to Mr. Lowe's sole supporter, "B. & W.," all we remember of his connection with that hive was in his making a reference during the "superposing" controversy in an

article of his we read on a railway journey, wherein he referred to the "crown board" of that hive, feeling evidently posed as to its position, and at a station we passed a hurried reply, and at the moment forgetting your much-valued contributor was not a brother Scot, used as the aptest phrase that came to hand that of "taking the brooks off a Heeladman," which we ever regret, as he has never alluded to the Stewarton since, consequently we may assume his experience is alike limited. "But you quite forget the authorities," says Mr. Lowe: "are they not grand?" We have as much respect for anyone for the honeyed names; but would your correspondent at leisure quote the passages from all or any who refer to, much less condemn, my favorite hive the Stewarton?

Before closing have been asked to reply to fresh queries about my competitive straw hive. What a fund of information has been dug from its recesses! how many have been taught! It is positively refreshing how the informer has been re-informed therefrom. Mr. Lowe finds fault it had not been wrought *la Pettigrew*. Now, I beg to acquaint him and all readers my aim is to produce as much super honey as possible from my stocks. Thought I had already mentioned, had it been so wrought strictly on such principle two swarms would have emerged, and the "honey result"—the contents of the beautiful glass which so enamoured the table of my friends—would have been frittered away in the construction of the comb of aforesaid frames, which (1875) was so had a season here they would both have died before autumn unfed, as well as the parent; but Mr. Rainford thinks what a gain there would have been had the hive been a full-sized *Pettigrew*. Similar if not worse results would have followed. The honey which I did manage to divert owing to the comparative small size at first *la Stewarton* to the super would have disappeared in comb-building in the *Pettigrew*; and so successfully was it managed the lightness of the body bore indispensible proof, a task Messrs. Lowe and *Pettigrew* will find not quite so easily accomplished when they take to stori-fying. For fuller information as to the evils attendant on employing too large straw skeps in a poor district, I refer Mr. Rainford to an able article by an esteemed correspondent, "R. S." vol. xxiv, where he will find that that gentleman was obliged to entirely abandon them, yielding little else than bees and empty combs in his county (Dumfriesshire), a much better than ours. As to this hive Mr. Lowe farther remarks, "I had no idea that so advanced an apianist as 'A RENFREWSHIRE BEE-KEEPER' would have such an antiquated piece of furniture in his apiary." For once Mr. Lowe has guessed right; not exactly my style, an incomer from his friend Mr. *Pettigrew's* native county of Lanark, one of three purchased there unseem. When they came I did think that however universal Mr. *Pettigrew* supposes his large skeps to have spread over Scotland, "a prophat is not without honour save in his own country," as of old.—A RENFREWSHIRE BEE-KEEPER.

[We have been obliged to omit part of the above communication from want of space.—Eds.]

STRAW SKEPS VERSUS BAR HIVES.

In the *Journal of Horticulture* of October 12th an account was given of the harvest of super honey which I obtained from one set of Stewarton boxes—*i. e.*, 144 lbs. of perfectly pure virgin honeycomb. A brief narrative of the subsequent history of the hive may interest some of your contributors. The two last supers were removed early in August, and the stock then occupied three 7-inch body boxes. They remained undisturbed until October, when it became necessary to prepare for their winter campaign.

The lowest box was first removed. This had been given to the bees as an empty box early in June. It was quite full of comb, but contained scarcely any honey. Out of eight combs the two outer are attached to 1½-inch bars, and are intended only for the storage of honey. Four of the interior combs were composed exclusively of worker cells; the remaining two combs were about half drone and half worker cells.

The upper box was next overhauled, and proved to be almost completely filled with sealed honey and pollen; there was hardly an unsealed cell in the whole box. The four central frames were removed, and after the bees had been shaken and brushed off the combs the lids of the cells were sliced off, and the combs put into one of Abbott's centrifugal extractors, and 6 lbs. of honey was thus obtained. All the pollen, and a considerable quantity of honey owing to the comparatively low temperature, remained in the cells; but the combs thus relieved of a portion of their superfluous treasure were then returned uninjured to the bees. The centre, now the lowest box, was finally examined: it contained a considerable store of honey, of which a large portion was unsealed for present use.

From this single colony I thus obtained in one session 144 lbs. of pure virgin super honeycomb, 6 lbs. of fine run or slung honey, and a box of excellent empty comb, which can either be returned to the bees as it is, or be used as guide comb for new stock combs. In addition to this, the colony which has yielded this harvest is

still amply provided for and will not require any feeding. In 1875 this colony, as previously stated, yielded about 80 lbs. of super honey and required no feeding after one of the worst honey seasons ever known in this district. Mr. *Pettigrew* seems to make light of this; but had he been in this locality he would have found numbers of hives, both stocks and swarms, dying of famine in the middle of July. No honey was accumulated after the middle of June.

In conclusion, I will remark that after the honey had been removed from the central combs in the top box, the bees who had previously clustered most densely in the box beneath ascended en masse into the upper storey, and, after they had cleared the combs and re-arranged their stores, took full possession of the box, and seem to have made it their quarters during the winter. Both boxes are, however, pretty well occupied. Last winter (1875-6) the bees occupied only the upper box.—J. E. BRISCOE, *Albrighton*.

OUR LETTER BOX.

Books (C. H. S.).—Davy's "Elements of Agricultural Chemistry," edited by Mr. Shier.

Address (J. Tomlinson).—We cannot state the address. If you enclose a stamped letter here and open we will forward it.

REMARKS.

23th.—Very bright and fine all day, but the coldest day this year, taking it as a whole.

1st.—Colder after than the preceding day, but very bright and pleasant, getting gradually more warm toward night, followed by rain at midnight.

2nd.—Rain in night and early morning; fine from 10 A.M. to noon, after then 3rd.—Showery all day, and very warm. (damp and showery.)

4th.—Dull and showery all day, rather better towards night.

5th.—Very bright, with slight frost early, continuing bright end fine till 4.45 P.M., when it suddenly clouded over, and at 5 the darkness was almost awful; it only lasted a very short time, during which rain fell, and by 5.30 all was as bright as before.

6th.—Fine pleasant day, though rather cold early.

Mean temperatures nearly identical with last week. Sharp frost at the beginning of the week being compensated by considerable warmth on 3rd and 4th.—G. J. SYMONS.

COVENT GARDEN MARKET.—MARCH 7.

No alteration in our market worth quoting. Trade very quiet, and very little coming to this market.

From observations taken near London during forty-three years, the average day temperature of the week is 50.1°; and its night temperature 33.8°.

AURICULAS.

IN the florist's Alpine Auricula the two great properties in colouring are—first, the shaded petal; secondly, the golden centre. This is the old-established rule, and it holds good still, and is not to be lightly set aside. Flowers possessing both these properties in perfection must, as regards colour-points, rank as first-class Alpines. Those which possess the first, but are weak in the second, are comparatively second-class varieties. They are represented by a number of shaded flowers with centres pale in colour, like so many custards more or less short of egg, and sometimes of the whitest whity yellow.

A third division has sprung up, possessing indeed the golden centre, but completely wanting in the leading point of shading. They have been called "Self Alpines," which although to florists a contradictory term, yet expresses them exactly. They combine the solid body colour of the self proper with the golden centre of the proper Alpine, and so do not really belong to either, but are a mixture of the two. If they are shown in either class they should be on an equality with the flowers of the class, or their position becomes a foregone and depressing conclusion; and if they are exhibited on an equality with either selfs or Alpines (being as much one as the other), then that established class, hitherto distinctly defined and thoroughly understood, has to be altered, diluted, loosened, and pulled down from its high standard to accommodate a perplexing and most prolific laxity. This should not be the spirit of the times.

The shaded flower is undoubtedly the truer "Alpine;" and shading combined with the golden centre is the strongest form of the flower. Where it is judged by competent judges and by recognised rules all its weaker types must cause some anxiety. At the least, the shaded petal is a point, an addition; it must go for something; I have stated its worth. It seems that flowers without it should be relegated to a separate class whose position we must leave Alpine growers to determine. These yellow-centred selfs need not be lost sight of; but the question is whether it is right that they should be made to confuse existing well-known class distinctions in florist sections of the Auricula. My friend Mr. Douglas also asks us what right we have to make such a distinction; and I might ask, What right have our brethren in the south to confound it?

If an Alpine may or may not be shaded, or a self may or may not have dense white paste, and any new combination between the two may rank with either, the worth and virtue of the best flowers are unprotected. "Self Alpines" are exceedingly pretty, but then there is not a member in the whole family they belong to otherwise than beautiful. This being so, we must, for distinction and honour, mark out certain combinations of beauty more or less difficult to obtain, in order to have rank and contrast, in order to have pull and resistance enough to give us storage way. With no right to make distinctions

and no obligation to abide by them, all florist law and order are at an end, showing and judging helplessly confused, and the encouragements to produce seedlings of rare merit gone.

Mr. Douglas as a true florist will, I am certain, feel this. I am sure he understands that every stern point demanded in a classic flower adds to the grace and beauty of that flower, and Nature works with us and for us to bestow each gift. Who obtained the first approach to an edged Auricula is probably a fact never to be recovered from the oblivion of prehistoric floriculture; but the history repeats itself in every batch of first-rate seedlings where some are selfs with just a tip or fringe of green or white round the petal edges.

And why do we discard the pin eye but for this, that the flower is infinitely fuller of sweet expression with a tube well-furnished with golden anthers than with a hollow throat out of which the naked pistil protrudes almost like a serpent's tongue? In the one case there is the light of a bright eye full of life, in the other the cold stony stare of a sculptured one. I think we have the right to draw and maintain these distinctions, small and unintelligible as they may seem to the uninitiated.

I am sorry to see now and then those who are certainly not florists themselves, nor presumably conversant with florist flowers, undertake in various floral papers to find fault with the florist and to hope he will grow less particular. Why! they owe to those very principles which florists work upon that they have Ribston Pippins for dessert and not Crab Apples.

Mr. Douglas invites an explanation why we should let one class of flowers override another and equally beautiful one. Well, the one may be much more difficult to obtain than the other, through having more points of merit. The greater the time and skill required to gain an object the higher the value of the thing attained. I think this is why green edges in Auriculas override the selfs, and why a feathered Tulip overrides the plain "breeder." They are the higher and more honourable forms, though the preference casts no slur upon the less-gifted flowers. All are full of beauty in their way, but you cannot say there is no difference in degree, no reason why one should rank before another.

Auriculas are to be shown in London with sticks to the trusses. I concede cheerfully that Alpines with their slender stems may require this, but not the Auricula proper. The insuperable objection to sticks is that they hide that important property of the plants, the possession of a firm, elastic, self-supporting stem, and they also conceal a sin against good culture; for a careless grower may draw his plants, and a stick save him from the penalty. How anyone can fancy a support, the crutchiness of which cannot be hid, improves an elegant plant able to carry gracefully its own head erect I cannot tell. However, our brethren down south rather admire wooden legs than otherwise, and their courteous recommendation to use them at their show will of course be gracefully complied with. But to see the plants thus is like seeing a friend sitting in exhibition form for his photograph—sticked like

the Anricula with the apparatus behind that grips him by the head, and is no doubt much to blame for those forced attitudes and stiffnesses in which we all "come out" so little like our own natural easy upright selves.

As to the improved border *Polyanthus* competing with our refined old sorts as florist flowers I do not think they can do it yet. They have not yet attained, as far as I am aware, the purity and depth of colour, the breadth and smoothness and uniform light yellow of the eye, or the perfect gold-wire lacing round and down the petals that mark the florist flower; they are rough imitations, I have seen them nothing nearer. The old florist *Polyanthus* may yet be grown gay with many heads of bloom—witness *Cheshire Favourite* and *Lord Lincoln* in black grounds, and *Kingfisher* and *George IV.* in red. But our *Polyanthus* wants seeding-up. Most of the old sorts are extinct; but seedlings from those I name would possess vigour enough and quality that could not now be surpassed.

Like Mr. Douglas, I write all this in no captious spirit; I simply offer a reply as candid as the questions he has asked in brotherly friendship, and he knows me well enough to believe that I would not wittingly use one acid word.—F. D. HOENER, *Kirkby Malzeard, Ripon.*

KITCHEN GARDENING.

MR. MACINDOE gives excellent advice in the remarks published on page 161. If any young gardener, or old one either, has not read the article to which I refer they have omitted what will benefit them to remember and practise. A thorough knowledge of how to produce a continual supply of first-rate vegetables is a really valuable attainment, and no gardener who does not possess this will ever retain the esteem of his employer. Where there is a garden at all there is sure to be a kitchen garden, consequently every young gardener has an opportunity of learning in this department, so that I do not think it is for want of opportunity that anyone need be ignorant of kitchen gardening; but I fear that many consider it drudgery, and this is a great mistake, as anyone may feel as much interested in the kitchen garden and its work as in growing *Orobolids* or any fine specimen plants. Many young gardeners are compelled to pass a certain amount of their time in the kitchen garden when they are serving their time, but as soon as this is over their leading idea is to get into the house, from whence it is considered to lower their dignity to return until they may be appointed to some charge of their own, when their deficiency of kitchen gardening is very often the cause of their failure. I can say from experience that a good knowledge of kitchen-garden work will cover a multitude of other deficiencies, but I pity the man who depends on his knowledge of specimens and housework to carry him through the requirements of a general place.

As the present is the most instructive period in all the year for kitchen-garden work I would strongly advise all young gardeners to pay great attention to all that is done in this department. Do not think that by looking "through the glass" that you know all about how the seeds are put in, but, if necessary, express your willingness to go out and make yourself useful in these busy times, and never rest satisfied until you know how long it takes each vegetable to come to perfection, the tillage, manure, &c., which suits each best, and all the different ways of getting some things in early and others late.—A KITCHEN GARDENER.

NOTES FROM MY GARDEN IN 1876.—No. 3. GREENHOUSE.

THERE cannot be much to say of a structure some 20 feet by 12 with a small annex, and yet there are a few noteworthy things to record for the benefit of "little men" like myself, who are obliged to make shift, and who wish at the same time to have something at all reasons to look at. This seems to me preferable to going in for a house full of bloom at one time and comparatively empty at another. You may have it gay with *Azaleas*, or *Cyclamens*, or *Pelargoniums*, or *Fuchsias*, but if you give your house up exclusively to one or other of these flowers it is very much like the bedding-out in the open garden—you sacrifice continuous enjoyment for the sake of one grand flush of bloom; and hence my effort has always been to secure a supply of flowers on which the eye may dwell with pleasure, and especially during the earlier months of the year.

Camellias were very good with me; the buds did not drop

and the flowers were fine. I attribute this to three causes—the obtaining of Mr. Epps selected peat, which is really a great boon to small gardeners; the keeping of the plants in the house all the year, never standing them out of doors; and the use of Standen's gardener's manure two or three times when the buds are swelling. A shift out of doors in the shade is congenial to the *Camellia*, but the danger is that watering is either overdone or neglected, and then when one is looking for the buds to open they become brown and drop off; whereas when in the house under the shade of the Vines they are not liable to the vicissitudes of weather and can be more carefully looked after. Amongst the few that I am enabled to grow I was particularly struck with *Madame Ambroise Verschaffel*, most beautifully flaked with rose. There were some blooms of that which might well have passed for a rose flake *Caration*, and without the need of any dressing.

I have already drawn attention to the beautiful class of bulbous roots—the *Ixias*, *Sparaxis*, and *Bahianas*. The former of these especially it is almost impossible to praise too highly. They are so elegant in form and habit, and so beautiful in their colouring, that I have been induced this year to grow them still more; and they are so thoroughly appreciated, too, for cutting for decoration, that they ought to be more grown than they are.

Another class of bulbous plants remarkable for their quaintness and beauty I had a few of last year, and owing to the kindness of Mr. Bull a larger number this year. I allude to the *Californian bulb*, *Cycelobothra* and *Calochortus*. They are utterly unlike anything we have had as yet; are said to be perfectly hardy, and, if not that, they are certainly most easily grown. *Cycelobothra cernula* is very lovely, and *Calochortus venustus* is a gem; but indeed all are very beautiful.

I had as usual sent me from Slough the new varieties of *Pelargoniums*, a class of plants the neglect of which one must ever more and more deplore, for they are very lovely, and for two months at least give a continuous and brilliant bloom. With one exception all those sent out last year came from the garden at Clewer, whence Mr. Foster has for so many years sent forth so many fine varieties. Some of my earliest floral associations are connected with them, and one must only hope that some day there may be a revival of the taste. There is improvement from year to year, although small, yet on looking back and comparing those of the past season with those, say, of 1873, the improvement is seen.

Ambassador (Foster).—A flower in which the spot does not cover the whole of the upper petals, but is of medium size, the petals being deep pink, while the lower petals are a lighter shade of the same colour.

Archduke (Foster).—In this the upper petals are entirely covered with deep maroon with the exception of a narrow wide edge of deep orange; lower petals are pink, slightly veined; centre pure white.

Aurora (Foster).—Brilliant fiery scarlet; a remarkably high-coloured flower with a medium spot. The plant at once strikes the eye even amongst others of a similar shade.

Challenger (Foster).—Scarlet petals with maroon spot. An attractive flower.

Diplomatist (Foster).—Top petals deep maroon; lower petals purple with a clear white eye. A very fine flower, and free in growth.

Enchantress (Foster).—Crimson pink, with dark maroon upper petals; clear white centre.

Gipsy (Foster).—A very dark flower, meriting its name. Very dark top petals with a narrow crimson margin; centre white; lower petals very richly painted.

Judith (Foster).—Upper petals dark maroon; rosy pink lower petals, white centre. Flower full and large.

Mrs. A. Matthews (Matthews).—A beautiful soft rosy-coloured flower; centre white; very smooth and even.

Potentate (Foster).—Maroon top, deep rose lower petals. A very lovely flower.

In addition to these Mr. Bréchant, who is an enthusiastic grower of this class of plants, sent me three or four small plants of seedlings of his own raising, amongst them a pure white flower which I think will be highly prized as a stage flower, and which will I believe appear in Mr. Turner's list of new varieties of this spring.

I have found some difficulty in filling up my house after the *Pelargoniums* were out of bloom, but last year managed by the help of *Lilies*, *Fuchsias*, and the bulbous-rooted *Begonias* to keep it tolerably gay. The latter are very useful and handsome, and such kinds as *Vesuvius*, *Model*, and others of a like

strain are a great boon. They are easily grown and very gay. Thus from January until the end of September I have been enabled to make my little house presentable, and have had much enjoyment for myself and pleasure for others out of it.—D., Deal.

RUST ON GRAPES.

I HAVE often read of and heard discussions relative to the cause of rust on Grapes. I think it has come to be generally believed that sulphur applied to hot-water pipes when the berries are in the embryo state will produce rust; others again say that damp hands while thinning, touching the berries with hair of the head, cold winds, &c., are the causes. I am not going to condemn all that has been said regarding the rust, but will express my opinion as to a principal source of its origin.

It is pretty well understood that thrips is very fond of the juices of the Vine, and this pleases their taste best when the wood, leaves, and fruit are in the young state. At this stage thrips are exceedingly busy (of course I allude to those only who have a stock of that troublesome little pest), preying on the young berries as well as the wood and leaves. I am decidedly of opinion that this is one of the principal causes of rust. Although to the naked eye the injury is invisible for a time, nevertheless damage is done, and it will make its appearance more and more while the berries swell until they have nearly attained their full size. No doubt by painting hot-water pipes or flues with sulphur the fumes will hasten the incrustation on the Grapes in the same manner as it will kill warts on the back of the leaves; but notwithstanding, had the damage not been there previous to the application of sulphur I am convinced it would do no harm unless applied very hot. If sulphur was the cause of rust, why are some of the berries of bunches quite clean and others bad with rust? One would imagine that all of the berries are subject to being affected by the fumes.

The most effectual cure that I have found for thrips is smoking with tobacco or tobacco paper. As our vineries are never clear of plants, and adhering to the old adage that "prevention is better than cure," we fumigate before commencing forcing, and periodically throughout the season. This is the most effectual and economical plan in keeping the Vines clean. Those whose houses are very much infested with thrips must fumigate three nights in succession.—JAMES DICKSON.

CULTURE OF THE DAHLIA.

AFTER an interval of several years I am about to resume the culture of Dahlias—not for the production of flowers for exhibition, but for ordinary garden decoration; and it occurs to me that a brief explanation of how I intend doing this may prove useful to the many who are on the outlook for flowers, which, in addition to being really attractive and ornamental, possess the valuable property of being amenable to easy and inexpensive methods of culture.

I am starting with a selection of some forty varieties, comprising a few of each class—fancy, bedding, bouquet, and exhibition, my object being to secure diversity in the plants as well as in the flowers which they bear. The whole of them are "pot roots," or, in other words, the dried roots of plants raised from cuttings taken late last season (in August), with the special view of keeping them in pots to form an easily portable stock for propagation this spring. There are various ways of managing the propagation; that which I prefer is early in the present month to mix together some leaves and fresh stable manure for a hotbed, not a very hot one; 3 feet high is quite sufficient to afford the gentle but steady bottom heat that is necessary to induce the quiescent tubers to put forth roots and the crowns to send up shoots. Upon the hotbed is placed a frame consisting of four rough deal boards nailed together. It is nearly filled with rich gritty soil, into which the roots are turned out of the pots, a hurdle thatched with straw being the only covering, and even this is removed upon every fine day. As the young shoots appear they are taken off close to the crown, potted, and put in a propagating frame or pot along with other cuttings. Roots form quickly, and the young plants are soon ready for a shift into 4-inch pots, when they are taken to a cold frame, receiving all due attention in watering, abundant ventilation, and protection from frost and cold cutting winds.

My reason for giving preference to this method of propagation is that it is very simple and very efficient, the plants

resulting from it being far preferable to those raised by any other method, for the gentle yet steady heat that is constantly rising to the roots induces a slow yet certain growth, while the constant play of fresh air about the crowns renders that growth very sturdy and robust, presenting a striking and pleasing contrast to the delicate straw-like appearance of such plants as we sometimes see in pits and forcing houses.

The Dahlia requires generous treatment like most other plants of a free succulent growth, and with my poor soil I shall be compelled to use plenty of manure or fail outright. The very best soil for the Dahlia is a deep, rich, sandy loam. What an unobvious sound the phrase has belonging to it, and how often do we have it in our mouths or at the tip of our pens when we want to describe soil that is very fertile! Well, that is the soil which I have not, but which I shall try to imitate as well as I can. Plenty of manure and gritty matter mixed with my poor soil will do this sufficiently well, just as a few cartloads or even barrowfuls of road scrapings would answer the same purpose for the puzzled dweller in a suburban villa, to whom—if he were to ask me to describe the best soil for his Dahlias; aye, and for most other flowers—I could not do better than advise him to make a heap, or rather a deep bed, of such road scrapings as are gathered on every highway, and to plant them therein.

Planting should not be done until the end of May or beginning of June; then select and mark the position of each plant with a stake driven firmly into the soil and left as a permanent support throughout the entire season of growth. By this method the long fleshy tuberos roots escape the damage so often inflicted when stakes are driven in to support them after they are planted. Water will be given abundantly and frequently in dry weather, preference being given to sewage water or liquid manure so often as it can be spared. In autumn the plants will be cut down when decay sets in, the roots lifted, and kept in a dry shed or cellar till spring comes round again.—EDWARD LUCKHURST.

SPROUTING POTATOES BEFORE PLANTING.

LIKE every matter relating to gardening this subject has been largely written about in the Journal. I observe that some correspondents recommend starting Potatoes far into growth in a heated house before planting. I daresay many of your readers who grow both early and late Potatoes have no heated house to start them in, and if they credit all this starting process they must think their chances of successful Potatogrowing a hopeless one; but I can tell them and show some proof that they need have no fear on that score. I never put one of my tubers into artificial heat to sprout. I planted a large pit with two or three sorts of kidneys about the middle of January; the haulms are now a foot high, and a healthier lot of Potatoes I have not seen for a long time either under glass or in the open air. If sprouting is an advantage it should be most shown in the short dull days, and one would suppose that unless the tubers were far advanced in growth the haulm would be long in appearing, even with a little heat, at that time, but such is not the case.

I will yield to the sprouting advocates so far, as I do not plant the tubers with no indication of growth about them. Most of those I have planted have been sprouted about half an inch, and this was done in a way that everybody may practise. All tubers intended for planting are spread thinly out in a half-lighted cool place, such as is afforded in any ordinary shed. The shoots formed here are short and thick, and the points have a pink appearance. This is a healthy sign, and is never found in those sprouted in strong heat. Their pale colour is a sure indication of a severe check when they come to be planted in the cold soil; and while they are standing still between life and death, those slightly but strongly sprouted in a cool place will make substantial progress.—PRACTICALIST.

PRIMULAS.

I HAVE read with very great pleasure, and I hope profit, Mr. Abbey's very interesting notes on Primulas, and most certainly agree with him that "a greenhouse at this season of the year without Primulas is indeed poor." There is one point in this article respecting double Primulas that is so much at variance with my practice that I hope your correspondent will excuse me noticing it. Mr. Abbey is reported to say, "I would particularly note the great value of double Primulas which are now raised from seed.. I have some so

large and double as to be taken for named varieties, only the great vigour of the plants and their floriferous character soon dispel any such suspicion."

Permit me to say I now have Primulas worthily occupying 16-sized pots. So vigorous and healthy are these plants that the rims of the pots are completely hidden; and as to their floriferous character, I have this day counted 110 flowers fully expanded on one plant, and twice that quantity of buds. Mr. Abbey mentioned Prince Arthur which I have from seed, but it is only semi-double. The Primulas in question were struck last April, and are quite as double as Daisies. I shall be happy to send Mr. Abbey a few flowers, but as I intend exhibiting cut flowers at Kensington on Wednesday the 21st inst., they cannot be spared until after the exhibition.—R. GILBERT, *Burghley*.

PRESERVING SEEDS FROM BIRDS.

SEED time brings more than one anxiety to the gardener. Bad weather makes it impossible to sow many crops at their proper time, and many other obstacles make spring progress anything but plain sailing; but of all pests and misfortunes there is none more aggravating than to have the seeds carefully placed in the ground and then to have them scatched up and voraciously eaten by the birds. Many schemes have been put in operation to avoid this. Nets form a safeguard, but everyone has not the means to possess a quantity of these; besides, resting them on the soil rots them, and there is much work entailed in putting them on and off the seed beds. I have been sowing a lot of Cabbage, Cauliflower, Lettuce, and other seeds that birds are fond of; and although they abound in flocks in the woods all round the garden, there is not one of them ever goes near a seed bed. I have spent no time in contriving "bogies," but all I have done is to scatter enough fine white lime over the surface of the beds to make them appear white. Why it is I cannot say, but not a bird will alight on this. Apart from the birds, snails have a strong aversion to the lime, so that it is as good as "killing two birds with one stone."—A KITCHEN GARDENER.

[We have observed the same results. The white surface is objectionable to birds, and sometimes also to owners of gardens, or we think the practice of dusting the surface of the soil and the branches of fruit trees with lime would be more generally adopted.—EDS.]

COCKSCOMB CULTURE.

At the usual fortnightly meeting of the Darlington Gardeners' Institute, the following paper on the *Celosia* or Cockscomb was read by Mr. Hilliard of Greencroft East:—

"The *Celosia cristata* is an old and a very favourite annual. The seed may be sown in a warm house or hothed at any time from the 1st of January to the end of March, or early in April, according to the time the plants are required. As soon as they are large enough to handle they may be pricked-out in pans or boxes, using well-enriched soil—namely, loam, leaf soil, and manure in equal parts, with sufficient sand to make the whole porous. Place them close to the glass in a brick hothed, and shade from bright sunshine. When they are well established and large enough pot them singly in 5-inch pots, using the same compost as before. Never allow them to become dry, or all your labour will be lost, for they will never forget the check they receive if watering be neglected, and all your after care will not compensate for that omission. When the 5-inch pots are well filled with roots give them the final shift, and plunge again in bottom heat, very carefully shading them for a few days; for if exposed to hot sunshine they will lose their lower foliage, turn brown, and be spoiled. When they have reached maturity they may be gradually hardened off and placed in any light airy structure, where if watched carefully and syringed occasionally to keep off the red spider (which is very apt to attack them), they may be kept good for two or three months. Before I come to the pyramidal varieties I would advise those who wish to grow *Celosias* for late blooming to be very careful about the drainage, as in the dark dull autumn days they are apt to decay at the neck if not well drained and carefully watered.

"The pyramidal section, commonly known as '*Celosia pyramidalis*,' requires somewhat similar treatment in their earlier stages, and somewhat similar soil. But if good and neat plants are wanted, sow early and strike cuttings, as by this mode dwarf pyramids closer set than if grown from seed may be obtained. Do not, however, adopt this plan with *Celosia cristata*, for it

will not produce such good combs as if grown from seed, and is too much dwarfed by the process. Very good specimens of the latter, pot and all not exceeding 12 or 14 inches, dwarf enough for any purpose, may be had from seed. To return to the pyramidal varieties, it will generally be impracticable to grow them to perfection in bottom heat, but this may be attained by having them in any warm house, if a genial moist atmosphere be maintained and they are not allowed to receive a sudden check. If, however, you have the former at command by all means avail yourself of it, and they will amply repay you for it and any extra care you bestow on them, as in the dull autumn and winter days their bright colours are very cheering and are a splendid contrast to foliage plants. They must be moved as required, and strong plants may be put into 10-inch pots, in which fine plants large enough for any purpose may be grown. Select drooping or weeping varieties for your best plants. I do not mean weeping to the same comparative extent as a drooping Ash or Beech, but those with the plumes slightly drooping. A few erect kinds should be grown for the sake of their plumes, as they make a desirable variety when intermixed with the pendulous varieties. The latter, are, however, best for all decorative purposes, as they usually grow much closer than the erect growers, which are apt to become straggling. When the plants show signs of bloom they may be watered with weak manure water; this will strengthen them, and bring them to perfection. In conclusion, I would advise all who require plants for conservatory decoration to grow *Celosia pyramidalis*; it may be safely classed among the brightest of winter decorative plants, and is of easy cultivation."—(*Darlington and Stockton Times*.)

MESSRS. ROLLISSON'S NURSERY, TOOTING.

Amongst the metropolitan nurseries worthy of notice for its long-established character and the extent and completeness of its collections of plants must be placed the head-quarters of William Rollisson & Sons. Being situated in the suburbs of London, just as they were beyond the smoke line, the nursery has the advantage of pure air, which is essential to the health of the great variety of hard-wooded plants which are cultivated, and it is also convenient of access from the stations of Tooting on the South-Western Railway, and Balham on the Brighton line.

The nursery, which may be described as a wholesale and retail plant emporium, contains a considerable number of glass structures—thirty large houses and numerous long ranges of pits and frames. These structures are occupied with stocks of plants of a very varied character—from *Orchids*, *Palms*, *Ferns*, and choice stove plants to *Heaths* and other hard-wooded greenhouse plants; also hardy herbaceous, alpine, and aquatic plants, *climbers*, *Roses*, &c., all of which are grown on an extensive scale.

There is nothing of external grandeur connected with the nursery, for its aspect is plain, the several houses having been erected for use rather than ornament; yet the more modern structures are not devoid of attractive features. The most imposing building is doubtless the show house or conservatory—a somewhat narrow and lofty span-roofed erection, which cannot be less than 350 feet in length. A bed is formed along the centre of the house with a pathway round it, a stage being arranged on one side next the glass for flowering plants, the other side being an opaque wall covered principally with *Camellias*. The central bed is occupied with large *Palms*, *Tree Ferns*, *Arancarias*, *Camellias*, &c., and is bordered with *Lycopodium denticulatum*, the side stage being gay with *Epicurians*, *Azaleas* (*A. mollis* being particularly attractive), *Lilies*, *bulbs*, &c., margined with *Isoplepis gracilis*, and the effect produced is very pleasing. The *Tree Ferns* in this house are especially noteworthy, a large importation having recently arrived, the trunks being straight and clean, and every one starting into growth freely. They vary in height from 2 to 8 feet, and comprise all the most popular sorts—with the addition of a few which are comparatively rare—notably *Dicksonia Diplanthe*, a New Caledonian form of *D. Youngii*, with the *ra* densely covered with cinnamon-coloured hairs.

The next house is totally different in character, being a wide flat-roofed lean-to, probably 300 feet long, and entirely filled with *Heaths*. This class of plants constitute a speciality of the nursery, the stock numbering 160,000 plants in almost all sizes and extremely healthy. Many new varieties of *Ericas*, probably nearly a hundred, have been raised in this nursery—in fact, almost all the best representatives of this genus are

garden hybrids, many of which are frequently regarded as species. The new *Ericas* sent out last year by this firm are *Effusa*, *Opulenta*, *Ornata*, *Shannoni glabra*, and *Tricolor profusa*, all raised by cross-fertilisation. Other new varieties are now being produced. Such popular decorative kinds as *hyemalis*, *Willmoreana*, &c., are raised by the thousand. The stock of the former at the commencement of the season numbered sixty thousand. Many plants are grown in frames, and others are placed under a skeleton framework and are simply covered with mats in severe weather. Potting is now being proceeded with, it being considered desirable to complete the shifting of *Ericas* by the 1st of April.

Ornamental-foliaged stove plants are extensively cultivated, several large houses being devoted to them. Nearly all the new *Crotone*s, *Dracenas* (including *Willia's* hybrids), *Aralias*, &c., are being increased. *Aralia Veitchii gracillima* appears to retain its distinctly slender character, and a new green variety of great elegance is highly promising; it is not yet in commerce. Noticeable in one of the stoves is a fine plant of *Spathiphyllum pictum* in remarkably fine colour. This bold plant was introduced by Mr. Bull, and appears to improve as it grows older—a silent example for growers to follow. A fine old flowering stove plant, *Tabernaemontana coronaria flore-pleno*, is being increased largely. So free is it that plants only a few inches high are surmounted with a corona of flower buds. Gesneraceous plants are also grown extensively, some of the *Yuccas* being now attractive with their richly-spotted flowers.

Three or four houses are filled with *Palms*, many of the plants consisting of popular kinds for decorative purposes, while kinds more new and rare are also represented. *Cocos Weddelliana* is flowering, and the newest forms of *Kentias*, *Geonomas*, *Astrocaryums*, &c., are being established. *Palms* are becoming increasing popular, and deservedly so, for no plants can so long retain their fresh ornamental character in the dry air of rooms and corridors, and can better resist injury from changes of temperature.

Ferns are cultivated on an extensive scale, one house devoted to them having a novel appearance from the rafters being heavily clothed with *Ficus repens*, which is also at intervals trained across the lights, forming as it were a series of panels. It is thus grown for the purpose of affording shade for the *Ferns*. In this house is a fine stock of *Lomaria gibba crispata*, *Adiantum gracillimum* raised from spores, the plants coming quite true to character; but it is singular that in their early stages the pinnae are large, resembling *A. onestum*, the fronds produced subsequently only coming of the peculiar slender character which suggested the popular name of "Ganze Fern," which has been appropriately given to this *Maidenhair*. The newer *Adiantums*, *A. Semanni* and *A. speciosum*, are also represented, besides others "too numerous to mention."

A series of large light span-roofed houses are devoted to such plants as *Hedera*s, *Dracophyllum*s, *Pimeles*, *Correas*, *Tetrathecas*, *Aphelaxes*, *Gnidias*, *Azaleas*, &c. *Gnidia pinifolia* is especially worthy of notice from its free-growing character, slender foliage, and small yet conspicuous white flowers; it is a plant worth growing in every greenhouse. *Grevillea Priesii*, which was certificated last year, is seen in goodly numbers; it is both novel and attractive, and likely to become popular. *Azaleas* (umbrella-shaped plants) are in superior condition. Many of them had been planted out in the summer continental fashion, and potted in the autumn, and the treatment has evidently suited them, for no plants could be in better condition. *Camellias* are also numerous and good, home-raised and home-grown plants.

Orchids have a large share of attention bestowed on them, two large houses being devoted to their culture. All the popular kinds are represented, the plants being grown as cool as possible consistent with safety, and they are clean and in good condition. Amongst those now flowering are *Dendrobium Wardianum*, *pardalinum*, *Bosalli*, noble, *litiflorum*, *Faulkneri*, *crassinode*, and *japonicum*; *Oncidium sarcoodes* and *Cavendishii*; *Odontoglossum Cervantesii*, *C. decora*, and *Alexandra*; *Cattleya citrina* and *Wareowiczii deltoata*; *Vanda tricolor*, *Miltonia cuneata*, *Sophronites grandiflora*, *Saocolea calceolaria*, *Phalenopsis grandiflora* and *Schilleriana*, *Dendrochilum glaucum*, and several *Cypripedium*s.

As may be expected at the period of the year, the propagating houses are being fully taxed: large stocks of *Tea Roses* are being worked, also *Clematites* and *Vines*, many of the latter being already established in 6-inch pots.

Hardy plants of all kinds receive special attention here;

fifty thousand are kept in small pots plunged in ashes, and there are also large plantations of *Phloxes*, *Pyrethrums*, *Ponies*, &c. The demand for these plants is great and is yearly increasing.

The nursery is now under the management of Mr. Gower, whose name is a sufficient guarantee that its reputation will increase rather than diminish. To him, also to the proprietors, I am indebted for much courtesy during my hasty "look round."—VISITOR.

NOTES AND GLEANINGS.

At a general meeting of the Royal Horticultural Society, held on the 7th inst. of the present candidates were elected FELLOWS OF THE SOCIETY:—Mrs. Chisholm Batten, J. Brunles, C.E., Mrs. Chapin, W. Jas. Epps, C. E. Hamilton, Mrs. Mounsey Huysam, Major Horrocks, Mrs. Lloyd, Mrs. Maitland, W. H. Michael, Henry Micholls, Robert Mixer, Sir W. B. Riddell, Bart., Mrs. Russell Roberts, G. Morley Saunders, Frederic Sewell, and Andrew Stephen, M.D. The following were also elected guinea members:—G. Smith, Mrs. E. Maberly, Miss F. C. Catley, Miss Edmonds, G. W. Greenhill, R. Elliott, Lady MacArthur, Hon. Isabel Calthorpe, S. Sidley, and Lady Dorothy Nevill.

THE Council of the Royal Horticultural Society propose instituting at the Chiswick Gardens this season, under the direction of the Fruit and Floral Committees, comparative trials of the following subjects. Of vegetables: Tomatoes, Cabbages, Savoys, Turnips, new Peas, and new Potatoes. Of flowers: *Epacris*, *Gloxinias*, *Begonias*, *Cannas*, new *Zonal Pelargoniums*, *Stocks*, *Asters*, and new annuals. Fellows of the Society and those desiring to contribute subjects for this purpose will please communicate with Dr. Hogg, Secretary to the Society; or Mr. Barron, Garden Superintendent at the Royal Horticultural Gardens, Chiswick.

WHAT is said to be an ANTIDOTE TO THE POTATO DISEASE is SALU—a compound of sulphur and potassium discovered by Mr. Worthington G. Smith, the eminent fungologist, who has so perfectly investigated the economy of the *Peronospora infestans*, which is the mould that gives rise to the disease. We observe that Messrs. J. C. Wheeler & Son of Gloucester are the sole agents for Great Britain; and it would be well worth the trouble for all who are interested in this important question if they were to give the salu a trial this season. We should be quite prepared to publish any reports on the experiment as may be sent us.

THE PELARGONIUM SOCIETY holds its exhibition at the Royal Horticultural Society's garden, South Kensington, on the 20th of June. Members only can compete. There are twenty-four classes, in most of which three prizes are offered, varying in amount from £5 to £1.

It will be remembered that a first-class certificate was awarded last year by the Royal Horticultural Society to Mr. Wm. Bull for a DOUBLE EPACRIS, and the honour was well merited. Mr. Bull has since been fortunate in obtaining another and distinct variety of this new type of *Epacris*, and the plant now flowering at Chelsea is worthy of inspection. The flowers are pure white and perfectly double, the "pips" being about three-eighths of an inch in diameter, and having tubes much shorter than the ordinary single flowers. The flowering shoots are closely set with the miniature rosette-like flowers, and present a charming appearance. There can be little doubt that the intrinsic merits of these new double *Epacris* will render them as popular in their way as double *Pelargoniums*. Like the *Pelargonium*, the pips of the double *Epacris* do not drop off but shrivel on the plants—an admitted advantage when the flowers are employed in a cut state. The new *Epacris* is named *Oncemeflora nivalis*, and it is sure to be extensively cultivated. Another noticeable plant now flowering in this nursery is *Imantophyllum miniatum princeps*, the flowers being three times the size of those of the species, and are also better formed and more richly coloured—a great acquisition. Several *Orchids* are also flowering, and the *Cycads* and *Tree Ferns* always command attention.

We learn that the subject of BLIGHT OR DISEASE affecting the plants in the TEA PLANTATIONS OF INDIA has been brought prominently under the notice of the Agricultural Society of India, a letter having been addressed to the Society to the effect that the attacks of "blight and red spider" having become of such a serious nature on many *Tea* gardens both at Assam and Cachar, and especially in the latter

province, it is necessary that all possible information, with a view of mitigating the evil, should be obtained and made widely known." At a subsequent meeting of the Society the line of action proposed, subject to the assistance of those interested in the matter, was to engage the services of an entomologist from England for the period of two years, so that he might have time and opportunity to observe and carefully study the character of the several kinds of blight in their various localities, such observations to be published under the auspices of the Society.

— THERE was a full attendance at the monthly meeting of the Horticultural Club on Wednesday the 7th inst., and the following gentlemen were elected members:—Charles Lee, Crosby House, Hounslow; H. J. Elwes, Preston, Cirencester; John Smith, Royal Gardens, Kew; H. G. Quilter, Birmingham; Benjamin R. Cant, Colchester; James F. West, Lynn-mouth Lodge, Reigate; and William Lee, Brandenburg Road, Gannarsbury.

— WE briefly announced in our report last week that the Floral Committee of the Royal Horticultural Society awarded a first-class certificate to Messrs. James Veitch & Sons for *EURYLELES AUSTRALASICA*. This plant deserves more than a casual notice from its distinctness and value for decorative purposes. It has been compared to an *Eucharis* and a *Criminum*, but it is more intelligibly represented as a *Paneratium*—indeed, it was once known as *Paneratium australasicum*. It is easy to be described. It has a bulb similar to a *Narcissus*, which throws up one or more heads of flowers 6 to 8 inches high and as large as those of an *Agapanthus*, but of a pearly white with yellow anthers. The leaves are produced occasionally with the flowers, but generally afterwards; they are 5 or 6 inches across and are of the same texture but lighter in colour than those of the *Eucharis*. *Euryleles australasica* was introduced from New Holland more than half a century ago, but its full merits have only just been established. It is a plant of easy culture, and appears to flower with great freedom; it lasts also a considerable time in beauty—fully a month under good management. It will be grown by the dozen and hundred when it becomes sufficiently known, and is likely to be as popular as the *Eucharis*.

— MANY striking Orchids are now flowering in Messrs. Veitch's extensive collection at Chelsea. Foremost must be named the grand *Lælia Veitchii*, a cross between *Cattleya labiata* and *Lælia crispata*. L. Pilcherii, from L. Perrinii and L. crispata, is also very attractive. *Lycaste alba maxima* commands attention from its wax-like substance and purity. A fine contrast is afforded by *Bletia amethystina*, purplish pink and very free. *Cattleya amethystoglossa*, with its richly spotted sepals, is very fine, and even finer from its size and its purity is *O. Trianae alba*. *C. citrina* is also just expanding. *Madevalia chimera* is protruding its grotesque flowers, *Stanhopea-like*, from the bottom of the basket in which it is growing, and *M. tovarensis* attracts by its purity. *Phalenopsis* and *Odontoglossums* are numerous, as also are *Dendrobiums*, including *D. Dominii*. Amongst *Oncidiums* the soft yellow of *aggregatum* commands attention, and even more so does *O. varicosum*, which is exceedingly fine, and the plants are in hundreds. Of the new and strikingly spotted *Odontoglossum cirrhoosum* only one plant is now in flower out of a stock of probably ten thousand. The collection of Orchids in this nursery is not more noticeable for its magnitude than for the remarkable clearness of every plant.

— "A LOVER OF BIRDS" writes to us as follows:—"Last season was marked by a scarcity of Holly berries, and 'haws' were not particularly plentiful. These form the staple of the food of the soft-billed birds in severe weather. Provisionally the winter has been mild and wet, and worms and slugs have been unusually active; upon those the blackbirds and thrushes have feasted, and did not eat the 'haws' until the frost and snow of March, when the worms and slugs had sought shelter in the earth. An entomologist has recently observed that the protracted wet has possibly proved fatal to insect life. May we not also presume that more than the usual quantities of grubs have been devoured by the birds during the extremely mild winter? Birds only eat haws, &c., in winter, and fruit during summer when deprived of the natural food by severe frost or extreme drought; therefore do not wantonly destroy the gardeners' friends—the birds."

— THE unusually mild weather and long-continued wet of the winter season appears, says an experienced gardener, to have had a marked effect upon the production of FORCED MUSH-

ROOMS. In no season have they been more abundant, the beds more enduring, or the quality better. This points to the necessity of providing regular humidity and an equable temperature in Mushroom culture, conditions which are better afforded in underground houses than in structures above ground. Artificial heat and frequent waterings, according to the evidence of the closing winter, should be as much as possible avoided in the cultivation of Mushrooms.

— WE recently noticed superior examples of double *Primulas*, also *Montauk Primulas*, as growing at Messrs. E. G. HENDERSON & SON'S PINE APPLE NURSERY. We may now say that this nursery is undergoing various improvements, and is being stocked in a manner worthy of its ownership. Large collections of ornamental-foliaged plants, stove and greenhouse flowering plants, Orchids, Lilies, Amaryllises, &c., besides several "old and rare" plants not commonly met with, are now to be seen at the "Pine Apple." Palms and Ferns are very numerous, the stock of *Adiantum farleyense* numbering 2500, while of the useful *Palm Corypha australis* there are four thousand plants. Orchids are also grown in large numbers, there being one thousand plants of *Odontoglossum Alexandræ*, and eight hundred of *Dendrobium thyrsiflorum*. Many Orchids are flowering, and we never saw finer varieties and finer growths of *Dendrobium Wardianum*, some of the flowers of this superlatively beautiful *Dendrobium* measuring 4 inches and more in diameter. *Hippastrum Hendersonii*, a beautiful variety, is becoming increasingly popular. It is grown by thousands in unheated pits during the summer, and flowers most freely during the winter months. A large number of seedling *Draecenas* are showing colour; and it is remarkable that while the whole of the seed was taken from one spray of *D. albicans* crossed with *D. pulcherrima*, both narrow-leaved kinds, the produce is extremely variable, many of the varieties being broad and massive in their foliage, and have little in common with their parentage. All the plants in the nursery are healthy and clean, and reflect credit on the manager, Mr. O'Brien.

— THE beautiful TREE CARNATIONS, GUELDER ROSE and ROSE PERFECT, for which first-class certificates were awarded at the last meeting of the Royal Horticultural Society, were exhibited by Mr. Charles Turner, Slough.

— WE have received the schedule of the INTERNATIONAL EXHIBITION to be held at Carlisle on September the 6th, 7th, and 8th. The schedule is divided into fourteen sections, comprising 228 classes. The prizes offered are very liberal, amounting in the aggregate to upwards of £1200. For collections of sixteen sorts of fruit the first prize is £20, for twelve sorts £15, and for ten sorts £10; £111 being provided for the twelve prizes offered in these collections. Grapes are well provided for, not less than £200 being offered in prizes. For eight varieties, one bunch of each, the amounts are £15, £12, £10, and £8. There are also seventy other prizes offered for Grapes. Liberal prizes are offered for Continental and American collections of fruit. The prizes offered for plants in pots are equally substantial, the chief being £20, £15, and £10 for twenty stove and greenhouse plants, and the same amounts for twelve new plants not yet in commerce. There are prizes also for cut flowers, table decorations, vegetables, and horticultural requisites. Several silver cups are offered by private donors, including three by Mr. V. Bull of Chelsea. The exhibits must be staged before 10 o'clock P.M. on September 5th, and must remain until one o'clock on the Monday following. Professional gardeners will be admitted on the first day of the Show from 9 to 11 A.M. on payment of one shilling each. The Exhibition is under distinguished patronage and a practical committee, and is to be managed by Mr. W. Thomeon of Clowdfords. Only fine weather during the Show days is required to render the great undertaking completely successful.

— UPWARDS of £1300 was realised by the recent sale of the late Mr. WILKINS'S ORCHIDS at Stevens's rooms. The principal prizes obtained were for *Lælia elegans* Turnerii, 36 guineas; *Odontoglossum vexillarium*, 23 to 42 guineas; and *O. Phalenopsis*, 29 guineas. Prices ranging from 10 to 15 guineas were secured for *Lælia arceuthoceras* Dawsonii, *Epidendrum vitellinum majus*, *Odontoglossum Binnii*, *Oncidium ampliatum majus*, and *Dendrobium Wardianum*.

— AT a recent meeting of the METEOROLOGICAL SOCIETY, the President, after referring to the various theories advanced to account for changes of climate, observed that the climate of London has been modified by the consumption of fuel and the vast population. He estimated that the heat developed from

the present annual consumption of 5,000,000 tons of coal on the metropolitan registration area of 118 square miles, and from all other artificial sources, would suffice to raise the temperature of a stratum of air 100 feet in depth resting on that area 2.5 every hour. The effect of the growth of the population of London from 900,000 at the commencement of the century to 3,500,000 at the present time, and of the still greater increase in the comparative consumption of coal, was manifested by the rise in the average temperature of the air at the Royal Observatory, Greenwich. For this reason Greenwich was not a suitable place for a meteorological observatory of the first order.

CLIVE HOUSE SEEDLING GRAPE.

We have been requested to publish the following:—

“To the Secretary of the Fruit Committee of the Royal Horticultural Society.

“Sir,—I beg to acknowledge receipt of extract from the minutes of the Fruit Committee of the Royal Horticultural Society respecting Clive House Seedling, and must express my astonishment that the Committee should have passed such a minute without first asking from me an explanation of the apparent inconsistency referred to.

“The whole of the seedlings raised by Mr. Bailey was from the same cross, the cross as given by me in my letter to the Committee. You may think it paradoxical when I say in the *Journal of Horticulture* that it is a founding; but I hold that the two statements are perfectly reconcilable. The first refers to the origin of my Vine, the second to its immediate relationship to the plants now at Alnwick Castle, as the rest of my letter clearly shows.

“In addition to previous evidence I have now that of Mr. Todd, head gardener at Rawcliffe, Langside, Glasgow, and formerly foreman at Alnwick Castle Gardens, who planted the Vine in question, and testifies that there were no other seedlings than those left by Mr. Bailey and known as his. My explanation, then, on this point is that my statement about the uncertainty of the parentage and connections had nothing to do with the original production of the Seedling, but referred to the immediate source—to the particular plant from which my plant was taken, and its relation to those now being declared to be the same under the abstract title of Cassey's Seedling.

“As for the name Clive House Seedling, which you may remember I reluctantly gave on the spur of the moment, I have no wish to maintain against the wish of the Committee if they look upon it as implying what I have never once pretended, that it was my own raising, and I am quite willing to adopt any name they may suggest, provided it should be free from local or personal bias.

“In closing I must strongly disclaim the charge of the Fruit Committee that I withheld the facts as to the origin of the Grape. My readiness to answer all questions, my immediate contradiction in the *Journal of Horticulture* of a groundless claim, and my full statement of the facts of the case, ought to have precluded such a charge; and I trust that the Fruit Committee will see their way to withdraw it and to place their withdrawal on their minutes.

“I have nothing to conceal. If required I am prepared to show that I obtained my Vines fairly and openly and am indebted to no man for them, and that I am not to blame if a mistake was made which gave me possession of this one and has preserved it from destruction. At the risk of unpleasant personalities I will if required defend my own name and property, and I trust that my present silence on personal transactions will not be deemed a withholding of the facts of the case. If the Fruit Committee have any questions to ask or any suggestion to make I shall give them my careful consideration.—I am, Sir, &c.—D. P. BELL.”

[The farther discussion of this subject may now cease. Everything has been said that can throw any light upon it, and that is all the public care for. We think the Fruit Committee did quite right in giving the new name of Alnwick Seedling, as this associates the Vine with the place where it was raised without any invidious reference to any person in particular.]

PRIMULA MINIMA.

VARIOUS are the popular names of this smallest known species of the genus; Smallest Bear's-ear, Smallest Auricula, and Snow Rosette are among them.

“It has been supposed to be extremely impatient of cultivation when removed from its natural abode, the tops of the highest mountains of the South of Europe, which it ascends to the limits of perpetual snow, at the elevation of 7000 to 8000 feet above the level of the sea.

“The corolla is large in proportion to the plant, and varies from pink to violet-purple and white; sometimes it equals all the rest of the plant together. The herb of the wild specimen is still more diminutive than in the cultivated one.

“Rootstock about as thick as a large quill, blackish when old; fibres white. Leaves cuneate, half an inch long, disposed in rosettes, very smooth, shining, coriaceous, deeply toothed at the end with pointed teeth. Scape obovately three-cornered, shorter than the leaves, one, seldom two-flowered. Involucre nearly of one piece, oblong, chafy. Calyx tubular, five-cleft; segments rounded, short obtuse. Corolla subsessile, often as large as all the rest of the plant together; faux furnished with a whitish nap; limb spreading; segments cleft in two for half

Fig. 25.—*Primula minima*.

their length like the letter Y. Capsule very blunt, shining.” —(*Botanical Register*.)

This species is not only noteworthy on account of its distinctness, but it has been found to have a tendency to cross with other species, and may be useful as a parent in raising new varieties of these increasing popular flowers. *P. Flörkeana* is the result of a cross between *P. minima* and *P. glutinosa*. It is a little singular that while *P. auricula* is a prolific parent, it has been found that a cross between it and *P. minima* cannot be effected.

QUEEN ONION FOR SPRING SOWING.

A FAILURE of part of the autumn-sown Onions has induced me to procure an extra quantity of the seed of Queen Onion, and to sow a few ounces of it upon a sheltered border with a

southern aspect in February, for the purpose of keeping up the supply at that critical period when the autumn-sown crop becomes exhausted and the regular spring-sown bed is still unfit for use, as will undoubtedly be the case this year. In such an emergency the quick growth and early maturity of the Queen reader it of especial value. By the time the young Onions are large enough to handle the soil may fairly be expected to be dry enough to enable us to transplant them from the seed bed. This plan is sometimes adopted for the general crop, and very successfully too. It is advisable for its economy, no seed being wasted; and in such a wet season as this, timely sowing may be done on a specially prepared border while the main quarters are yet wet and sodden.—E. LUCKHURST.

FICUS PARCELLII FRUITING.

This plant was fruited here in 1875, and since that time young plants have produced fruit profusely, having borne Figs in all stages of growth. This is one of the finest of decorative plants when well grown, and should have a place in every collection of stove plants.—RICHARD NISBET, *Asuarby Park Gardens*.

P.S.—Mr. B. S. Williams of Holloway showed a plant of it at the Crystal Palace in fruit the same year.

We have a plant of this which bore sixteen fruit last summer. The fruit is of the size described by your correspondent on page 176, and when ripe are beautifully striped and mottled. We have also some young plants which were struck from the above plant last August which are in fruit now. The fruit pushes from the axils of the leaves. *Ficus Cooperii* is also in fruit in our stores.—WILLIAM COOMBER, *Superintendent Royal Botanic Gardens, Regent's Park*.

INSECT PESTS.

MR. ANDREW MURRAY has applied to Government to aid in destroying the insects which destroy our crops. "He wishes to see some united active steps taken for clearing whole districts at once of pests. If united action could by any means be secured, the work would be simple. A scientific inspection of a district would decide, with regard to a particular pest, the condition of development in which it would be on certain days. Instruction would be given as to the course to be adopted, and if this were simultaneously acted on throughout a district, the pest might be checked if not entirely removed. It is sincerely to be hoped that either some society or the Department will take so important a matter up.

"The attempt is not new. It has been already tried on a greater or less scale, in various ways, and with more or less success both in this country and on the Continent—the degree of success being almost invariably correspondent to the care taken and the extent of the district subjected to the experiment. Its importance is, moreover, daily becoming better recognised. During the present year the governments of France, Belgium, and America all have had legislative measures on the subject before them. Switzerland has already acted, and Italy, it is understood, is about to do so.

"In France the destruction of hurtful insects has been long made compulsory by legal enactment. This attempt has hitherto failed from the unavailability and unworkableness of the law; but a new *projet de loi* is now before the Senate which is expected to remedy the defects of the old law. A full account of the whole progress of legislation on the subject in France is given in the *proposition de loi* on which the above *projet de loi* is founded. The "*Journal Officielle*" (of 28th June last) contains these documents.

"In Belgium a rural code is at this moment in preparation, in which power is taken to compel the destruction of insects, but it is reserved for royal warrant (*arrêté royale*) to direct the measures to be taken and the machinery of action.

"General and simultaneous voluntary efforts have been tried in many countries by offering prizes for the destruction of the injurious insects, enlisting school children in their search, &c., and where this has been done under the auspices of some central authority it has had good results. For instance, in 1868, which was a very bad year for cockchafer on the Continent, the central Agricultural Society of Saxony organised a scheme under which they made an energetic appeal to the land-owners, magistrates, manufacturers, &c., begging them to assist in getting the insects collected, and under that appeal vast numbers were destroyed. The difficulty, however, has

usually been to get a central authority of sufficient weight and authority and extent of influence to charge itself with the task.

"He would humbly submit that some such permissive measure conducted under the authority and direction of the Government would be best suited to the requirements of this country. Compulsory legislation is probably premature, and at any rate could be more effectively demanded if the permissive action had been tried and failed. A central directing authority is absolutely essential; if the experiment is to be tried let us use our best means.

"He would suggest that next year the attempt should be made in two or three counties to begin with. Cheshire, Lancashire, and Derbyshire have suffered greatly for some years past from the Onion and Carrot flies. Let the diminution or extirpation of these flies in these counties be the first experiment. A trial to that extent would neither be troublesome nor costly, and it would to a certain extent serve as a test and guide for further proceedings. All that would be necessary would be the circulation in these counties through the clergymen, schoolmasters, municipal authorities, and local papers, of an appeal urging every one to pull up and burn his infected plants (which are easily distinguished) on a particular day about a certain date, and to get the parochial authorities to take some trouble to see that this is done. Some brief lectures or explanations of what is wanted should also be given in as many parts of the counties as possible a few weeks previously.

"Two or three years' perseverance in such a course should gradually diminish the numbers of the insects; and the process, if successful, should each year be extended to other insects and other counties until the whole kingdom is embraced."

GLADIOLUS DISEASE.

ANYONE who thinks for himself and has the courage of his opinions, is sure at some time or other to differ from those who are engaged in the same pursuits as himself, and so although Mr. Kelway grows Gladioli by the acre, and I only by the hundred, we have never been able to agree on the subject on which he has written. I hope to discuss it by-and-by when I have more leisure, but I must ask of him kindly to say where in my little book on the subject I have said that it is contagious? I fancy I know the passage which has led him to this conclusion. At page 43 I have said, "I some little time back submitted some bulbs of Gladiolus to our most eminent vegetable physiologist, the Rev. M. J. Berkeley, who said it was a disease similar to that which attacks *Crocus cornu*, and is described in the Horticultural Society's Transactions as an ulceration of the corolla, similar to that which takes place in the Potato. No cause is there assigned for it. It is not fungous, although fungi come afterwards. It is contagious." All of which are Mr. Berkeley's words, not mine, and have reference to the *Crocus*, and not to the *Gladiolus*.—D., *Deal*.

NEW BOOKS.

Text-book of Structural and Physiological Botany. By OTTO W. THOM. Translated and Edited by A. W. BENNETT, M.A., &c. Longmans. 1877. Small 8vo., pp. ix. and 479, with copious illustrations.

A Manual of Botany (Anatomical and Physiological) for the Use of Students. By B. BROWN, M.A., Ph.D., &c. Blackwood. 1874. 8vo., pp. xviii. and 614, with copious illustrations.

It has long been remarked by examiners in botany that there must in general be some great fault in the mode of teaching, or students could not go up to a competitive examination so utterly ignorant of everything in the shape of practical knowledge. From the time when Professors Henslow and Lindley first commenced examining at the University of London great stress has always been laid upon this part of the examination, but, notwithstanding a continued practice of many years following out their view, examiners still make the same complaint. Students go up with a mass of book-work, such as it is; but if a common Hyacinth, Tulip, or Primrose is put into their hands, it has sometimes happened that not one of these common plants was recognised. Even a Primrose on the river's brim was not a Primrose to them; or, if known, it was nothing save a yellow Primrose. Now the cause of all this was believed to be an essential fault in the greater part of the manuals placed into the hands of students, and consequently a misapprehension on the part of instructors of the proper way

of teaching botany. It is a remarkable fact that two years since not one person who went up for the Civil Service of India, on the question being asked, was acquainted with Oliver's "First Book of Indian Botany," which could scarcely have been the case had not teachers been content to travel in the old beaten rut.

This matter has been brought painfully to our mind by the two publications at the head of this article; the former destined for school students, the other, in some respects less pretentious, apparently for a slightly more advanced time of study. Both begin with complicated questions as to the nature of cells and their mode of development, before an acquaintance has been made with the more apparent organs of a plant or the slightest knowledge of the objects about which the science is concerned, and the consequences is that the student is either utterly disgusted and throws up the matter in despair, or acquires a mere smattering of hard names and ill-digested facts, which he is willing to get by rote for the mere purposes of a competitive examination, with the foregone determination to throw the whole aside when it has answered his self-interest, without in the slightest degree doing what it was intended to do—as to opening his mind or giving him a taste for observing with profit the stray pleasures which are spread abroad with a bountiful hand, but are no sources of pleasure to the disgusted crammer. There is much philosophy in the words of the great French novelist, "I have always thought that it is more easy to descend from the whole to a part than to ascend from the part to the whole. It is a maxim of algebra that we should proceed from the known to the unknown, and not from the unknown to the known."

The translator of Thomé's text book has done his part in rescuing it from an objection which we should at once consider fatal in a book placed in the hands of English students, ignoring as it does almost everything that has been done in this country; for though comparatively little attention is paid here to physiology, while we are however, on the contrary, strong in systematic botany, it would be easy to point out many exceptions, and Darwin at least is the prince of physiologists. But, apart from this, how can a boy obtain a clear knowledge from such disquisitions as that with which the first pages commence, where he will be left without anything save a confused conception of what a cell really is, and will run the risk of thinking that there may be a cell without any cell wall? It would be easy to point out matters in which the author is evidently wrong, but this is not our object, but to show that such treatises are comparatively useless as far as English students go, for we are not looking to what may be suitable to the current German mind; and if more advanced students want a manual, we should rather at once recommend Sachs's book, notwithstanding its acknowledged difficulties. Indeed, we are forcibly convinced of this in comparing the one with the other. Nothing is in general so unsatisfactory as a mere compendium. We do not deny that the book contains a great deal that is valuable, and the illustrations are for the most part good, and are often on such a scale as to make them more intelligible; but we cannot conceive that to a beginner such an illustration as that at page 57 and the accompanying text can convey any idea to a schoolboy. If the book is used at all, we should recommend beginning with the fourth chapter, and when that is mastered, with some practical comparison of well-known examples, it will be time to enter on the consideration of the more recondite structures.

The work of Dr. E. Brown, as regards the time of publication, appeared three years before the translation of Mr. Thomé's volume. As it comes from the hand of a man of great experience it may well be expected to contain much of interest, and it does not labour under the same charge of ignoring British authorities, as the copious references in the notes amply testify; nor does it attempt in one volume to adopt what he calls the time-honoured conventionality prevailing in text books.

"The science," he says, "has become now so extensive, that if the student is to have in a manual of this nature anything better than a mere smattering of the well-worn facts of science, so interlarded as to be most repulsive with technical names in use, obsolete, or which ought to be abolished, or rather never to have seen the light of print, it is impossible to crum into one moderately sized volume anatomy, physiology, classification of the natural orders, palmo-physiology, and phyto-geography. Either the volume must become inconveniently bulky, or the outline given so meagre as to be really useless." With this we entirely accord, and we only wish that our author had followed

the example set by Oliver in his lessons in elementary botany, in which case his volume would have appeared in a useful contrast with many other manuals. It would be here again easy to point out faults; but in so extensive a science, where every day is modifying what was supposed to be accomplished yesterday, and in some cases wrong notions might be accepted—as, perhaps from inadvertency, the student might be led to conclude that the elaters of Jungermannia and the so-called elaters of Equisetum are of the same nature, from the reference which is given to the figure. But, as said before, this is not our object, but to call especial attention to the best mode of studying and teaching botany, convinced as we are that till some change is made in this direction we shall have still in the greater number of cases the same unsatisfactory results. Still less do we wish for a moment to detract from the valuable mass of information which, in many other respects, this excellent volume contains.

EXHIBITION PANSIES.

MR. MILLER'S contributions on Pansies have afforded me much pleasure. When one reads of special societies for the encouragement of different florists' flowers—Chrysanthemums, Carnations, Auriculas, &c., surely something may be done for the purpose of giving an impetus to the cultivation of a flower so beautiful as the Pansy. Is it not possible to offer prizes—adventitious prizes—for Pansies at some of the special shows? If it is, and competition could be stimulated, those shows would be rendered additionally attractive, and visitors would have an opportunity of enjoying such flowers as they little dream of being in existence. Florists would then be able to appreciate the efforts of such men as Meers, Downie, Dicksons, Hooper, &c., who have done so much in rendering our gardens attractive and furnishing varieties of Pansies of such sterling merit.

Pansies are, I fear, not sufficiently appreciated in the south, but the time must come when their claims will command the attention of all lovers of hardy flowers, and the heat and drought which are supposed to be so inimical will only be regarded as incentives to further effort in perfecting the culture of flowers which are worthy of a place in every garden in Britain.

In the north Pansies are regarded as amongst the most beautiful of hardy flowers, and when well cultivated they afford as much gratification to visitors as any other occupants of the garden. In the garden which has been under my charge for a number of years, and where flowers of all kinds are appreciated, those which give the greatest amount of satisfaction are Roses and Pansies.

I am particularly pleased to find that Pansies have such an able champion as Mr. Miller, and I shall anticipate with pleasure his promised editorial notes. I trust they will tend to dispel the delusion that Pansies can only be well grown in Scotland, and perhaps they will remind the patrons of florists' flowers in the south—Messrs. Dombrain, Dodwell, Douglas, &c., that there are other flowers worthy of their patronage besides Carnations and Auriculas. As to the mode of exhibiting I concur with "C. R. Notts," that Show and Fancy Pansies are sufficiently numerous and, in their sections, distinct as to merit separate classes. If exhibited in mixture the tendency would be to destroy the distinctive features of two clearly defined types of beautiful flowers, which I think is undesirable.

—A NORTHERN GARDENER.

MICE AND RED LEAD.

HAVING the valuable evidence of so large a number of experienced gardeners at your disposition you will perhaps scarcely care for that of a lady amateur. Still, I will venture to offer it as at least practical. Last spring I planted two rows of early Peas, having first thoroughly wetted them with linseed oil, and then shaken over them red lead until they were well coated. I placed wires over the rows and waited in expectation of the usual promising-looking green shoots. To my dismay scarcely more than one-third appeared, but ugly gaps of 10 or 12 inches were left, and on close inspection in these gaps I found many remains of my tenderly-cared-for Peas in the shape of roots and red skins. In vain I searched for spaces by which sparrows or even bluebirds might have entered, and was fairly puzzled until on a fine morning, lifting a seed pan placed on a bank some 30 feet distant, a hole beneath revealed two bright black specks, which moved, appeared, and disappeared—a mouse! Forthwith my sharp little terrier came to my aid, and turned out a nest of four young mice, and at

the same time certain vermilion-coloured skins, which too plainly explained the thievish propensities of another mouse.—
A KENTISH BEE.

GLAZING WITHOUT PUTTY.

AFTER seeing the article on this subject by a "STEWART AND GARDENER" I cannot resist the temptation to contribute my experience on the subject of glazing without putty. My opinion is that a "STEWART AND GARDENER" is treading in the right direction, and his nearly twenty years' experience ought to be received as conclusive evidence that glass structures can be made to exclude water partly without putty, and entirely without it on the top side. I think the past was a favourable season for trying whether any method of glazing will answer or not, for the number of rainy days and depth of rainfall since last September exceeds anything we have had in my recollection.

Last autumn I erected ainery 60 feet long by 9 feet wide, with the roof at an angle of 45°; and as I am only a working amateur and with limited means my study was for cheapness and effectiveness, two points which I think I have obtained

on which the glass rests and into the groove, and by having the square cut as shown each side of the sashbar would get its proper share of such condensation; but if the glass was cut with the bevels all one way, one groove on one side of the sashbar would have to take all the water and the other side none, which might not answer the purpose intended.

This notice of glazing without putty originated from an inquiry in your Journal of November 16th last year, signed "D. P. B.," who asked "if you knew of any vineries glazed with roof glass butted." I replied in your issue of November 30th that I could show a method of doing so from practical experience, after which I had many communications, which I replied to privately, not wishing to figure in the Journal at that time as an authority on the subject of glazing without putty and no lap; but since then a brick and tile manufacturer in this neighbourhood has created a large vinery and glazed the roof after this plan, and it answers well, although at an angle of about 35°. He has also brought out a new kind of flooring brick for vineries and greenhouses which can be walked upon perfectly dry, still in the indented pattern a quantity of water will rest for evaporation. The floor has a neat appearance, and no doubt when advertised this kind of brick will make its way into most new erections. I am now superintending the erection of a vinery 25 feet by 13 feet, with the roof at an angle of 40° to be glazed with lapsless squares and no putty, knowing that putty does more harm than good, especially on the top side of a sashbar.

Your readers will perceive the bevelled edge on which the glass rests, which is all-important in assisting any condensation to fall into the groove, also taking care the cap does not press hard upon the sprigs which keep the glass down. By using say four coats of Carson's anticorrosive paint on the top side of the sashbar before they are fixed there will be no fear of any wet penetrating the wood, but as I began with the subject of cheapness I must conclude so. My bars had two coats of gas tar and quicklime mixed to the consistency of thick paint and laid on the top side before they were fixed, which I have found in other work resists wet better than anything else. Your readers must observe that I am no gardener, but having a fancy for a vinery, and, like many other working amateurs with limited means, had to study cheapness with effectiveness—two things which I think I have obtained, and the few hints I have given here on glazing may be a benefit to some amateurs who feel a pleasure in doing the work themselves.—THOMAS HARDCASTLE, *Valuer, Boroughbridge, Yorkshire.*

DR. ERASMUS DARWIN.

His baptismal name did not influence his mental convictions. He was no Erasmus in Christianity, and so devoted himself too exclusively to an acquaintance with second causes. He was a native of Elton, near Newark, Nottinghamshire, where he was born December 12th, 1731. After going through the usual school education under the Rev. Mr. Burrows at the grammar school at Chesterfield with credit, he was sent to St. John's College at Cambridge. There he only continued until he took his bachelor's degree in medicine, when he went to Edinburgh to complete his studies, which being finished and having taken the degree of doctor in medicine, a profession to which he was always attached, he went to Lichfield and there commenced his career of practice. Being sent for soon after his arrival to Mr. Inglis, a gentleman of considerable fortune in the neighbourhood who was ill with fever and in so dangerous a state that the attending physician had given up the case as hopeless, the doctor had the good fortune to restore him to health. This gave him so high a degree of reputation at Lichfield and in the neighbouring towns and villages that his competitor, who was before in considerable practice, finding himself neglected and nearly deserted left the place. Dr. Darwin soon after married Miss Howard, the daughter of a respectable inhabitant of Lichfield, by which he strengthened his interest in the place. By this lady he had three sons. In 1781, having married a second wife, he removed to Derby, where he continued to reside to the time of his death, which happened on Sunday the 18th of April, 1802, in the seventieth year of his age. Six children by his second lady, with their mother, remained to lament their loss.

The doctor was of an athletic make, was pitted with the small pox, and he stammered much in his speech. He had enjoyed an almost uninterrupted good state of health until towards the conclusion of his life, which he attributed, and reasonably, to his temperate mode of living, particularly to his

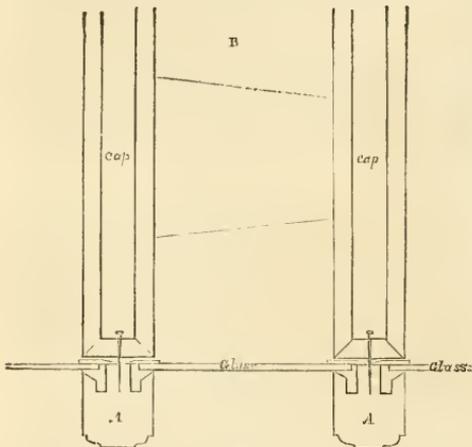

Fig. 26.

in the method of glazing. But I go a little further than a "STEWART AND GARDENER"—I have used no putty and no lap, and if I could have commanded a wet season in order to try whether my method of glazing would answer or not I could not have been better accommodated than I have been during the past four months; yet scarcely a drop of water could I see from the roof, and not one from the squares where they join. And in furtherance of the object I have in view—namely, to assist all working amateurs like myself, through your journal, who like to follow my plan in glazing with lapsless squares, I send a section of my sashbar A, which is quite plain and can be made of any desired strength according to the size of the vinery. My sashbars are 3 inches by 2½, with squares 24 inches by 14, 21-oz. glass, which are simply fastened down with four wrought-iron sprigs (copper would be better) at the corners of each square. The cap is nailed on with four 2-inch nails with the heads left out a quarter of an inch, so that they can easily be drawn and the cap taken off should a square get broken and require renewing; then it is only letting the squares above the broken one slide gently down, putting the new square in at the top, so that they may all fit close at the joints. Other minor details in this method of glazing will easily be seen by anyone who will give his attention to the subject.

If I had another roof to glaze the only thing I should alter would be to have the squares cut 1 inch out of square where they join edge to edge, or, in other words, to have them cut bevelwise (as per sketch N), so that any condensation underneath the glass or any oozing through the joints from the top side would find its way to the side of the sashbar, and by having no putty underneath and with the unevenness of the glass will allow the condensation to fall on to the level edge

moderation in the use of fermented liquors. This practice he recommended strenuously to all who consulted him.

His frequent journeys into the country on professional business contributed also in no small degree to the preservation of his health and his faculties, which latter remained unimpaired to the day of his death. His death was sudden, occasioned by a fit of what he was used to call *angina pectoris*, which he had several times experienced, and always relieved by bleeding plentifully.

As Dr. Darwin was a votary to poetry as well as medicine, he occasionally sent his effusions in that way to one or other of the monthly publications, but without his name, conceiving, from the example of Akenside and Armstrong, that the reputation he might acquire by his poetry would operate as a bar to his advancement in the practice of medicine. His "*Botanic Garden*," in which he celebrates what he calls the "*Loves of the Plants*," the first of his poems to which he put his name,

was not published until the year 1781, when his medical fame was so well established as to make it safe for him to indulge his taste in any way he should choose. Besides, the poem was so amply furnished with notes containing the natural history and accounts of the properties of plants, that it did not seem very alien from his profession. The "*Botanic Garden*" is comprised in two parts. In the first the author treats of the "*Economy of Vegetables*" in the second the "*Loves of the Plants*." The novelty of the design, the brilliancy of the diction, full of figurative expressions, in which everything was personified, rendered the poem for some years extremely popular.

In 1793 the author published the first volume of "*Zoönomie*, or the *Laws of Organic Life*," &c. The second volume, which completed the author's plan, was printed in the year 1796. As the eccentric genius of the author was known, great expectations were formed of this work, the labour

Fig. 27.—DR. ERASMUS DARWIN.

we were told of more than twenty years. It was to reform, or entirely new model, the whole system of medicine, professing no less than to account for the manner in which man, animals, and vegetables are formed. They all, it seems, take their origin from living filaments susceptible of irritation, which is the agent that sets them in motion. Archimedes was wont to say, "Give me a place to stand on and I will move the earth;" such was his confidence in his knowledge of the power of the lever. Our author said, "Give me a fibre susceptible of irritation and I will make a tree, a dog, a horse, a man." It would be useless to enter into an examination of the *Zoönomie*, which has long ceased to be popular. Those who wish to see a complete refutation of the sophisms contained in it will read with satisfaction "*Observations on the Zoönomie of Dr. Darwin*," by Thomas Brown, Esq., published at Edinburgh in 8vo. in 1798. In 1801 the author published "*Phytologia*, or the *Philosophy of Agriculture and Gardening*;" but the public, tired with the reveries of the writer, let this large book of six hundred pages in 4to. pass almost unnoticed. As little attention was paid to a small tract on female education, which had little indeed to attract notice.

We are admirers of the poetry, as well as of the scientific

forecastings of Dr. Darwin. He made common topics attractive, as when he wrote—

"There are of learned taste who still prefer
 Cos Lettuce, Furragon, and Cucumber;
 There are who still with equal praises yoke
 Young Peas, Asparagus, and Artichoke;
 Beaux there are still with lamb and Spinach nurs'd,
 And clowns eat Beans and bacon till they burst.
 This loom I ask of Fate, where'er I dize,
 O be the Proteus form of Cabbage mise;
 Kale, Colewort, Cauliflower, or soft and clear
 If Broccoli delight thy nicer ear,
 Olive, rural Muse! the culture and the name
 In verse immortal to the rolls of Fame."

He foresaw the future when he penned—

"Soon shall thy arm, unconquer'd Steam! afar
 Drag the slow horse or drive the rapid car;
 Or on wide-waving wings expanded bear
 The flying chariot through the fields of air."

AURICULAS AND THE WOOLLY APHIS.

I HAVE to thank my friend Mr. Horner for his note and good wishes on this subject, and am sorry to say that I did not read his notice of it in the October number of the "*Florist*

and Pomologist," or should have been on the look-out. I grieve to add that to all appearance I shall lose one-half of my stock—a sad loss at all times, but doubly so under the circumstances of the proposed Exhibition at the Crystal Palace, and after having had last season the finest bloom I have had for many years. I am going next week to attend to them, and will then say what I have found. Have any of your correspondents seen the insect?—D., *Deal*.

SEDUM SPECTABILE.

SOME time ago my name was mentioned in the Journal in connection with this fine *Sedum*, and as it is becoming such a popular plant, and just the one for an amateur to grow, I will state a few particulars about it. In the first place, I bought two plants which had been struck in the spring while they were in bloom. After flowering had ceased the stems were cut off and the plants were planted out in the rockery. When February came there were numerous little shoots springing up from them, which when large enough were taken off and rooted in pots under a hand-glass without heat. These were potted, and the tops of these again were taken off and rooted in the way above described. The plants which were struck first pushed many shoots—too many for such young plants, therefore I thinned them out to about three to each plant, and made cuttings and rooted them. These were grown in pots till the bedding arrangements were made, when the late-struck plants were planted out in beds by themselves, and they flowered late, commencing in August and continuing throughout September; their foliage was also very attractive, being different to any other plant in the garden. Every visitor admired the plants, and I have received many inquiries respecting the qualities of this *Sedum* as a flower-garden plant.

My reply is that it is a very beautiful plant and can hardly be put out of place. It does for bedding by itself, or among subtropical plants it is very effective. For growing as a single specimen in the herbaceous border I know of no plant more acceptable; and in vases, too, it thrives remarkably well and looks noble and attractive. As a pot plant there is very little trouble in growing it, and in all situations it will thrive, and I may safely say in common garden soil. My plants have been in the ground two years and have stools more than a foot over and are shooting up very thick, I shall therefore thin out the smallest of the growths, and the others will grow up the stronger and produce fine heads of flowers. Mr. Robson has also grown this plant in splendid condition at Linton Park.—T. RECORD.

[Mr. Record has done well by directing attention to this valuable hardy herbaceous plant, than which few will better reward for high cultivation.—EDS.]

ASPECTS OF NATURE—FEBRUARY.

DURING February we have almost the first indications of spring. A mild sunny day at this time appears to change the aspect of nature as if by magic. While the sky was grey and overcast all nature appeared clothed in the same sombre tint, but a glint of sunlight on heathside or brook brings out each swelling green bud in bright contrast to brown leafless stem and bare branch, and seems to impart joyous life to every ripple on the water. The Hazel still hangs out its pretty yellow tassels; and in sheltered copse and warm spots on hedgerow banks the wild Honeysuckle and the common Elder push forth the first green leaflets. The Snowdrop, "the early herald of the infant year," peeps forth in our gardens, and mild open weather will give us this beautiful harbinger of spring in clustered profusion, drawing our attention from their desolate surroundings to contemplate their pale pendulous bells, which tinkle fairy-like with every breath of wind and bear a streak of green on every petal, as though they, the first flowers of the year, bore a touch of Nature's favourite universal colour as a distinctive badge.

The birds come with the flowers. The robin, that constant friend of man, has cheered the dreary winter mornings and early afternoons with his joyous if not thrilling pipings. Now, too, the woodlark, one of the earliest and sweetest songsters of the grove, begins to trill his melodious song; while the harmony of the fields and woods is rendered still more entrancing before the end of the month by the full, rich, enchanting notes of the blackbird and thrush.

In strong contrast to the inimitable songs of the smaller birds we have the hoarse cawings of colonies of rooks, which

now begin to pair, and appear to let the world in general know they contemplate commencing housekeeping at once from the incessant noise and fuss they make over building their nests. The wonderful instinct with which all living creatures are endowed is sufficiently apparent in the building of rooks' nests, as these birds break with their strong beaks from the living trees the young green twigs pliable and full of sap: dead sticks could not be interlaced with the same facility, nor would they bear the weight of such heavy birds.

On south walls the flowers of the *Pyrus japonica* are all aglow, the beautiful rich scarlet blossoms having none of the pale delicacy of tint so commonly ascribed to the early flowers of spring. The Crocuses also show no lack of colour, and seem to have guarded, from the time of their planting deep down in the brown earth, the gold and purple of autumnal skies, to bring these gorgeous tints to gladden our hearts in early spring.

The unexampled mildness of the season has this year made February exceptionally rich in the number of plants in leaf and bloom. Such frosts as have occurred have had but little effect on the general forwardness of vegetation. In many places the Elder trees are as green as in early summer, and the wild favourites of March have come to us before their time. White and purple Violets are in full bloom, Primroses may be gathered in abundance, the Mezerion is in flower, and in appearance the month has many of the characteristics of March.

As a rule February is a wet month, and this season has proved no exception, save that the "icy bonds" have been conspicuous by their absence. The poet's description is as true to nature as of yore—

"Now shifting gales with mild influence blow,
Cloud o'er the skies and melt the falling snow;
The softened earth with fertile moisture teems,
And, freed from icy bonds, down rush the swelling streams."

In very rural districts, where on high banks and hedgerows Gooseberry and sometimes Currant bushes have taken root and grow up among the Hawthorn, the bright tender green of their early foliage is very conspicuous.

During the moist warm days of early spring headlands and byelanes are in many places carpeted with the bright green leaves of the Ground Nut. The foliage of this little-regarded wilding is invaluable for bouquets and vases at this time of year; its Fern-like character and exquisitely delicate green tint make it most suitable for arranging with the more carefully tended blossoms of the greenhouse.

The seedtime is at hand, and in preparation for its advent the farmer hastens forward the work of preparing the land; and Virgil's description is as applicable now as when it was written so many centuries since—

"While yet the spring is young, while earth unbinds
Her frozen bosom to the western winds;
While mountain snows dissolve against the sun,
And streams yet new from precipices run;
E'en in this early dawning of the year
Produce the plough and yoke the sturdy steer."

—T. S. J.

THE "BROWNTAILS" AGAIN!

ALREADY have I occupied some small space in the Journal on two occasions, when I have been referring to the economy of the Brown-tail Moth as it came under my observation in a district of North Kent. Though I do not wish the reader to suppose that I have "Browntails on the brain," I have continued to watch the habits of the colonies of the Brown-tail (*Liparis chrysothæa*) which reside in the vicinity of Gravesend and Chalk. The increase in numbers that was notable in 1875 as compared with the two preceding years was not followed up in 1876 by a still larger accession of caterpillar devourers, and the reason, I apprehend, was this, that many of the broods died off, wholly or partially, during the cold spring and the unfavourable summer of 1876. But yet I see at this moment far more colonies than I could wish to see studded over the Hawthorn hedges awaiting the bursting of the April buds. Thus, for instance, in one part of a road where the hedge is made up of shrubs standing at eight intervals apart I counted twenty-four nests upon one bush, representing at the moderate average of fifty to a nest, more than a thousand caterpillars to attack the foliage by-and-by. It is a curious circumstance in the history of the Brown-tail caterpillar, that though they are gregarious the whole brood descended from one parent do not usually form one family. The mother moth in the process of egg-laying seems generally

to shift her quarters two or three times; hence few nests are found to contain more than eighty or a hundred individuals, some perhaps not more than twenty or thirty. Of course it is possible that in certain of these instances the small parties are the survivors of larger colonies which had started on the emergence of the caterpillars from the eggs.

The question was put by me whether any gardeners could state from their own experience that they had found the insect injurious either to fruit trees or to the Rose, as has also been insinuated against it. If the absence of replies is not conclusive evidence in favour of the harmlessness of the species so far as Britain is concerned at present, it at least tends to show that no person has any better accession to make. Yet the Brown-tail has an undeniably bad repute; a century or so ago it occasioned alarm in many parts of England, and even had the honour of a pamphlet devoted solely to its history, containing an amusing farrago of fact and fiction. The late Edward Newman assured me that he regarded the accounts published concerning the ravages of the Brown-tail, which accounts have often been referred to in entomological and horticultural books, as largely made up of mis-statements; but, then, it is also true that on the Continent, even to this hour, the species does prove itself a nuisance. In a letter I received from Mr. Doubleday of Epping during the spring of 1874 he mentions that a friend who had been in the south of France saw the Brown-tail caterpillars travelling by millions on the paths and roads, the authorities having to employ men to sweep them up on account of the annoyance they caused. Going about in that way there cannot be doubt that they "meant business"—that is to say, they were in search of food, and not likely to be very particular as to what Rosaceous plant they settled upon.

In various places in Kent, especially in localities not far from Gravesend, fruit culture is a matter of importance, and the proprietors of orchards and market gardens ought to be on the alert to ward off any enemy of which the inroads can be anticipated. Nothing is easier than to deal with Brown-tail caterpillars in the winter or spring, before they have begun feeding; and though in the hedges colonies are on the Hawthorn, Blackthorn, and wild Rose, yet when these hedges are in proximity to fruit trees, however tender of insect life we may be, I think anyone would be justified in reducing the number of the insect.

I should add that the Brown-tails in this locality are seemingly as yet confined to a few lines of hedgerow along the old Dover road near Denton, at East Milton, and near the village of Chalk; hence with little trouble 90 per cent. could probably be cleared off by the judicious use of shears. And here a point of some nicety might be raised. Let us suppose B has on his hedges this or some other insect likely to be injurious to the gardening operations of C. B does not trouble about it; but C, finding B will take no measures which C deems requisite, appeals to A, from whom both parties lease their lands. Can A for the sake of his other tenant and for his own (indirectly) oblige B to take steps to remove the pest? It would seem in fairness he should have the right, or else to intervene if B is inert, and himself do what may be done in the case.—J. R. S. C.

OUR BORDER FLOWERS—FRENCH HONEYSUCKLE.

YEARS ago *Hedysarum coronarium* was treated as a biennial, and is so treated still by some growers. Strictly speaking it may not be a perennial, but lasting from year to year as it does, and reproducing itself freely from seed, I have no hesitation in placing it as a perennial. The subject in hand is a strong grower and requires staking; it is then a fine object when well established, rising to the height of from 3 to 4 feet. Its handsome foliage, pretty red flowers and delicate perfume, claim for it a prominent place, especially where cut flowers are in demand, for it bears cutting well, continuing in bloom for a long time. It is a capital plant for shrubbery borders and open spaces, where, if desirable, it may be pegged down, and in that way it flowers as freely as when trained upright. *Hedysarum coronarium album* is a grand acquisition and ought to be in company with *H. coronarium*; when grown together they produce a fine effect. *H. roseum* is of much dwarfer habit and is desirable as a rock plant; *H. argenteum* with its silvery-grey appearance is not to be despised. *H. venustum* is, comparatively speaking, of recent introduction, but none of the family appear to attract much attention, as they are very

seldom met with. They are not at all particular as to soil or situation. The place intended for them should be well broken up to the depth of 2 feet, for, being strong deep-rooting plants, they require depth to develop themselves. They may be increased by division, but they are much better raised from seed sown in spring or summer, the plants being thinned-out and transplanted as the cultivator may think best.—VERITAS.

GARDENING IN ILLINOIS.

MR. B. O. ARMIST states in *The Prairie Farmer*:—"My aged mother, eighty-eight years of age (one of the two only persons living who were settled in Edgar county in 1818) has witnessed the rise and progress of our horticulture from its commencement to the present time, and with the weight of these many years resting upon her she reviews it with much pleasure, and often reminds me of the great variety of fruit that we now cultivate compared with what they had for years in the early settlement. She says that Nature was very kind to them in those early days in the profusion of her native fruits; that when she settled here, sixty years ago, the wild Strawberries grew in great abundance in the prairie. At my earliest recollection there was but a single variety cultivated in the gardens, and not much attention paid to these, as a supply of the fruit could be had by picking it on the common. The Hovey's Seedling was not received here from the east until 1838. It was a wonderful berry for that day. I have continued its cultivation along with many of the most noted varieties, and it is yet almost unrivalled in all its qualities.

"Wild Plums were also numerous in the forests and in the thickets, and could be gathered by the waggon-load, smooth and fair; not in the ruined condition we find them of late. Wild Grapes were plentiful, a small winter Grape according to the tops of tall forest trees, and the summer and fall Grapes spread over the shrubs and small bushes in the barrens and along the watercourses.

"The White Cape and Black Cape Grapes were the only cultivated varieties grown here for the first eighteen years of the settlement.

"In 1836 the Catawba, Isabella, Clinton, and York Madeira were introduced, all of which did well (fruit without a blemish) until 1853, when the rot appeared.

"Persons frequently called at the nursery for English Grapes, English Gooseberries, English Currants, English Plums, and English Mulberries, believing that all the fine fruit was of English origin.

"There were only six varieties of Pear known here previous to 1836. Of these the Mammoth, from the famous mammoth tree near Vincennes, Ind., was the queen of summer Pears, and as common on the farms of the early settlers as the Bartlett is to-day. The old Pound Pear, monstrous in size and easily grown, was king of the winter dessert, and we didn't know that there was any better variety. In 1836 my father received the Bartlett, White Doyenné, Flemish Beauty, Seckel, Julienne, Urbanist, and Colmar Van Mons, and by 1840 had collected over a hundred varieties of Pears.

"The following are the varieties of Apples that he brought with him to this country:—Winter Jannette, or Neverfail, Milan, Smith Cider, Yellow Pippin, Sweet R. I. Greening, Winter Queen, Black Gillyflower, Newtown Pippin, Hannah, Newtown Spitzenberg, Large Romantic, Little Romantic (Gillpin), Winter White, Lady's Finger, Hard Red, Shaker Red, and Priestly; Autumn, Rambo, Fall Winesap, and Harper's Sweet."

DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

HARDY FRUIT GARDEN.

THERE are few gardens of large size where it is not necessary to head down and re-graft Apple and Pear trees occasionally. Sometimes a variety that has been introduced to the garden proves to be either worthless or not true to name. The best way in that case is to cut the tree down (as has already been advised in a previous number) and re-graft it. When the branches are large the best way is to work the trees on what is called the crown-grafting system; two grafts should be placed opposite to each other. Small branches may be whip-grafted. The grafts should be tied firmly with stout wax and then be clayed over. There are several sorts of grafting wax used, but we find stiff clay the most convenient. It is mixed with a quantity of cut hay, and when well worked together it does not crack after being exposed on the trees.

Some of the old authors recommend root-pruning to be per-

formed at this season, and we agree with you to a certain extent, and would limit the trees to be operated upon to those which showed very exuberant growth indeed, and were not likely to bear any fruit during the ensuing season. It is now generally agreed amongst practical men that the best time to root-prune is in November, and the earlier in the month the better. If the root-pruning is done now it should only be partially, by cutting a few of the main roots and placing round them some maiden loam free from manure. So far back as the time of Evelyn attention had been given to checking the flow of superfluous sap in fruit trees; but it is not certain that cutting the long bare roots to cause the formation of fibres near the main stem had been thought of. Evelyn recommended to lay bare the roots in the winter; but this is a dangerous practice, and with our present knowledge could not for a moment be entertained. A mistake is sometimes made in pruning newly-planted trees by cutting them in too close. When Roses are bought in and planted one year old from the bud, we cut them back to two or three eyes; and the old writers recommended the same practice with wall trees two and three years old. If the trees have been under good management in the nursery they will be well furnished with fibrous roots, and when this is the case the shoots should be cut back to two-thirds of their length only.

The present is a good time to plant Fig trees. They may be turned out of the pots, and all the roots that are matted round the ball should be laid carefully into some good loam—clayey loam is the best, and it should not be too rich, as the tendency of the Fig tree is to run too much to strong unfruitful growths. The branches, being easily broken, should be nailed to the wall. Cuttings taken off with heels and laid in against the wall in some fine soil will soon strike out roots. If any newly-planted fruit trees away with the wind to the extent of loosening them at the roots some support ought to be placed to them.

It is not our best practice to put out Strawberry plants at this season, but many persons do so. The runners are selected in the autumn and planted closely together in beds. They are now starting into growth, and no time should be lost in transferring them into their permanent quarters in deeply-trenched and well-manured ground. Plants put out at this time will throw a few flowers and would bear fruit; but it is better not to allow them to do so. In suitable clay soil the same plants will continue in bearing for many years. In light, gravelly, or sandy soil they will do better if the beds are renewed annually. In that case the plants must be put out early in August.

PINE HOUSES.

Fruiting plants in the earliest house are now going on well; some of the fruit is considerably advanced, and a few plants have it just showing in the centre. Much attention is necessary as to watering. It will not do at all to allow the plants to suffer for want of water. We look over the plants twice a week, and give manure water for every second watering. The temperature at night when the weather is mild is 70°, and even with cold frost winds it is not allowed to fall below 65°. We have not yet been able to place the succession plants into their fruiting pots owing to the cold weather. No time ought to be lost in seeing to this if the plants are intended to fruit early next year. Now that so much foreign fruit finds its way to our markets the most profitable variety to grow is the Queen, and this is also by far the best for summer fruiting. It is not well to allow too many suckers on the old plants. About two to each plant will be enough, and if the plants are not required it is much better not to allow more than one. Queens throw up suckers freely, sometimes from six to nine cluster round the base of a plant. Smooth-leaved Cayenne and Charlotte Rothschild do not usually throw up many suckers. With a higher temperature and increased solar light and heat more moisture is necessary, and this is applied both from the evaporating troughs and by sprinkling the walls and paths of the house with water as often as may be necessary.

ORCHARD HOUSE.

The Peach and Nectarine trees are now in flower, and as the weather is unfavourable for the setting of the fruit, more care is necessary in seeing that the pollen is applied to the stigma either by shaking the trees twice daily or by using a small brush of camel's hair. It is better to use the brush for shy-setting sorts, and it may also be well to take pollen from, say, Royal George Peach, and apply it to the flowers of Exquisite or Walbourn Admirable. With us the blossoms of Nectarines set more freely than Peach blossoms, but it is better withal to shake the trees once a day, about 10 A.M. Pear and Plum trees have been taken into the house, but they are not yet in flower. We have always found Pears the most difficult to set, but when the trees are placed in the lightest part of the house with air freely admitted, and the atmosphere kept as dry as possible, the difficulty is overcome. None of the trees must suffer by want of water at the roots, and if this is the case the fruit is sure to set badly. The shelves all round the house are furnished with Strawberry plants in pots, and seldom have we had a better show for fruit; the crowns are very large and plump, and they are now bursting into leaf. The pots are occasionally supplied

with weak manure water, and as soon as the fruit is set on the trees we shall syringe them and the Strawberries freely to prevent the attacks of red spider.

PLANT STOVE AND ORCHID HOUSES.

There is now plenty of work in these structures, as with increasing light and heat many plants are starting into active growth, and these requiring to be repotted must be seen to without delay. It is much better to repot now than to let the plants make much growth, as they will then experience a considerable check. The method of potting and composition of the soils have been frequently described, and it will be unnecessary to allude further to it at this time. All free-growing plants ought to be repotted if they are in small pots and it is intended to grow them on. Cuttings put in some time ago will now be rooted, and ought to be potted-off into small pots. If there is any sign of thrips or aphids in the houses it is best to fumigate with tobacco smoke until the pests are quite destroyed. If a few of these escape at this period they spread rapidly and do considerable damage, and it is very dangerous to use tobacco smoke when the young leaves of tender plants or Orchids have just been formed. Mealy bug should also be carefully watched. It is very difficult indeed to eradicate it from any plants where it has gained a foothold, and when the plants have been washed again and again, and you think not a vestige of the pest remained anywhere, the ardent cultivator is surprised to find a colony of young insects between the leaves at the points of the young growths of a choice *Ixora*, or on the succulent shoots of *Stephanotis floribunda*. There is no way of cleansing the plants but by constant watchfulness and destroying the insects as they appear.

Caladiums are now at rest under the stages in the stove, but they will be taken out presently and be supplied with water, and when they have made a little growth will be repotted into the same sized pots. Plants of *Poinsettia pulcherrima* are at rest in a cooler house. At this time last year there was a goodly display of floral bracts, but, from what cause we know not, they have dropped earlier this year. There are many plants subject to the attacks of red spider, and it is always best to destroy or keep it under by syringing if the plants have foliage or flowers that would not be injured by the water. The shadings for the roof have been put up, and they are used when the sun shines strongly, but not more than is necessary, and they are let down for a few hours only at mid-day.

We have been repotting and rebasketing some of the Orchids. A few are better potted at this season, others when they start into growth in summer. *Calanthes* must be repotted as soon as they start into growth. Ours were potted a week or two ago, and are already rooting freely in the fresh compost. The old soil is entirely shaken away from the bulbs, and the potting material, which is good turfy loam with a little decayed manure added to it, is pressed firmly round the base of the bulbs. The species potted at this time are all the *vestita* section and *C. Veitchii*. This variety partakes of *Limatodes* roses in its nature, and does not always grow so freely as the *vestita* section, but it requires similar treatment. *Angulos Clowesii* has also been repotted in a compost of about equal parts of turfy peat, chopped sphagnum, and clean potsherds; the pots are also clean, and are filled rather more than half full of drainage. The Indian *Crocuses* (*Pliconeas*) have also been repotted; the compost is the same and also treatment as for *Angulos*. Several other species of Orchids have been repotted; we like to do this as they start into active growth. *Cattleyas* will still endure a fair share of sun heat, but if the weather should be fine and the sun strikes the glass directly about mid-day we shall shade; the blinds have been fixed ready.

Disa grandiflora is a splendid Orchid when well grown. We are sometimes told "that it will do well in an ordinary greenhouse;" it sometimes succeeds admirably. At Chateaufort under the care of Mr. Speed it may be seen growing with great freedom in an ordinary Heath house with very little shade. It has failed at Loddon under exactly similar treatment; and Mr. Werd of Leyton could do nothing with it as a greenhouse plant, but grew it fairly in the cool Orchid house. It requires plenty of drainage and to be potted in peat and sphagnum.—J. DOUGLAS.

TRADE CATALOGUE RECEIVED.

Francis & Arthur Dickson & Sons, 100, Eastgate Street, Chester.—Catalogue of Select Farm Seeds.

TO CORRESPONDENTS.

* * * All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

CHRISTIANITY SHOWS (W. S.).—We cannot publish such a list. They must advertise.

BOORS (C. F. Lamb).—London's "Encyclopedia of Agriculture."

PARAFFIN OIL (Juvenile).—Two wine glasses full of paraffin added to three gallons of water would not injure Orange trees at any time.

STRAWBERRIES (X. Y. Z.).—Vicomesse Héricart de Thury, Keens' Seedling, President, Sir Joseph Paxton, and Dr. Hogg.

ROSE.—Could the name of the Rose asked for by Mr. Luckhurst be Pierre de St. Cyr? I think he does not name the colour, but surely Gloire de Dijon is most well known to be so asked for.—C. R.

FORCING STRAWBERRIES (Essex).—We can best aid you by stating our practice. The plants grow in the house, but are introduced at fortnightly intervals in a bed, and planted 1 foot apart. We plant in March, dividing the old plants, securing at least one good crown, and it may be some smaller crowns to each division, and a fair amount of roots. They are planted so that the crowns are just covered with soil, which is light and rich, giving a mulching over the beds out an inch thick of short manure. The situation is open. In autumn after the leaves fall the plants are lifted and potted in 7-inch pots, and buried in ashes in a sheltered spot, and we introduce them as required to any heated house, such as a vinery started at the beginning of January. These plants flower in March, others being introduced at fortnightly intervals until April. They are very easily rooted in temperature of 50° to 55°, better if a few degrees lower to commence with. After they are in good foliage watering requires to be copious, liquid manure being given at every alternate watering. One half the plants only are taken up the first year, but remain in the house until potted; and in the autumn, the longest being dropped, they are taken up and potted into 9-inch pots, so that we have plants in 7-inch pots a year old, and others in 9-inch two years old. The latter are best, but they take up more room. The old plants are kept in a cold house or pit after flowering, not allowing them to suffer from want of water. In June those in 9-inch pots are turned out with the ball entire in rows a foot apart, and that distance between the plants; but those from 9-inch pots are cut in two, and if the halves have many crowns they are also cut in twain and similarly planted. They are well watered during dry weather, and usually commence flowering in the autumn, especially those which had not been divided. They are allowed to grow a year clear without being again forced. The cause of the leaves of your plants turning brown at the edges is no doubt due to the house having been fumigated. We always remove the plants from the house before fumigating, as no plants are so susceptible of injury from tobacco smoke as these, or the injury may have arisen from want of water.

VEGETABLES, &c., FOR SWAMPY GROUNDS (E. Highton).—If water floods in the winter no vegetable crop would succeed; otherwise from the most sandy soils it would be well to grow the following:—Cauli, Kale, Broccoli, Parsnips, and Celery. Plants most likely to thrive are *Acorus gramineus variegatus*, *Epiobolium hirsutum*, *Lysimachia threudica*, *Lythrum roseum superbum*, *Galbra palustris flore-pleno*, *Carex paniculata*, *C. pendula*, and *Mentha sylvestris trifidata*.

DRIVING WORMS OUT OF POTS (L. M.).—Place 1 lb. of quinine in a tub, pour over it three gallons of water, stir well, and let it stand forty-eight hours, then pour off the clear liquid into a watering pot. With a lump of rather stiff clay stop the holes in the pots, and saturate the soil for an hour. The limo water should rest on the soil, or it will not be effectual. The worms will either come to the surface or perish. Remove the clay from the drainage holes, and allow the limo water to run into a tub. Repeat the plan after the water has at the earliest opportunity. Soot water will not injure the Ferns nor destroy worms.

PRUNING AND POTTING BEDDING GERANIUMS (J. A. X.).—Cut the plants down now, but do not do it too closely, leaving a few eyes of last year's wood. When they are breaking freely, having shoots about an inch long, turn the plants out of the pots, removing most of the old soil, and set them in the same or slightly larger pots, watering carefully until the plants are in full growth. The cuttings turn black because you keep the surface of the soil too wet, or they may have been bruisd with the dibble in closing the soil about them. The plants require to be kept rather dry. We prefer inserting the cuttings in small pots singly, but they answer well if placed thinly around the sides of a pot.

TROPEOLIN SPECIOSUM (N. C.).—Shift your plant into a size larger pot and keep in a cool house until the middle of April or early in May, when plant out where required.

CULTURE OF DOCARDIAS (Idem).—Take cuttings in April, strike them in gentle heat, pot-off when rooted, and grow in frames. They may be placed outdoors in summer, but at the end of September the plants should be cut-in and potted after they have commenced growing, but they are not nearly so good as young plants.

STOPPING BEDDING CALCEOLARIAS—ZONAL PELARGONIUMS FOR WINTER FLOWERING (Idem).—Stop the Calceolarias to two joints and plant them out in 9 inches apart if the soil be poor, or 12 inches if rich. The cuttings of Geraniums should be potted singly in small pots, and stop them when they become established stopped, or if in pots stop them at once. Shift into 6-inch pots when they have made shoots an inch long after stopping, and stop again early in June. They should have after this a position outdoors upon ashes in a sheltered situation, and be placed in the blooming pots (6 or 9 inches) about the middle of July, the plants having been stopped about a week previously. In late August and early September weak liquid manure should be given twice a week; the plants should be placed under glass about the middle of September. To flower during the winter they require a temperature of 45° to 55° and abundance of light and air.

FORFONE ROSE (E. E., Wilt).—Write to Messrs. Curtis & Co., Rossby, Trowbridge, Wilt.

COCUBERS IN SMALL HOUSE (P. C.).—You ought to have sufficient heat from the flue, both for bottom and top heat; and as you do not say whether there has been any difficulty in getting up the heat, we can only conjecture as to the cause. It is very likely that the flues under the bed became too hot. It requires very little heat from a flue or hot-water pipe to heat a room, and the water in the pipes can be cooled by having a tank, in which the pigeon-holes allow part to escape to the house. Our own way is to place a good depth of bricks over the pipes for bottom heat. The internal atmosphere is heated separately from the other. We advise you to do this, and also to bring the flue into the side of the path; the one return flue, if the heat is not sufficient, will be quite sufficient for the top.

FAILURE OF CAPE IN VINERY (E. F. M.).—As your border is inside only perhaps it wants water. Could you not have the valve altered so that the heat would not pass through it? Vines must have a season of rest. A heavy crop last year would be in itself account for a partial failure this.

ROSES DAMPING (J. T. M.).—Now mature under the stage would certainly cause more moisture, which would naturally increase the evil. A dry heat is what you require, but if you cannot have this place the plants now to the glass, and admit plenty of air on all favorable occasions. If you can put in a stove it will do better. Flowers of sulphur and best way to have to get over leaf. Keep the soil in the pots moderately moist.

GREEN FLY ON STRAWBERRY PLANTS (A Constant Reader).—They are frequently attacked. Fumigate with tobacco smoke.

FORCING VINES IN POTS (Lxx).—One flow and return 9-inch pipe will be quite sufficient for bottom heat. No evaporating troughs are required on the pipes, but a bottom heat. Six feet lengths of 4-inch pipes should be fitted with troughs and water in the troughs and best way to have to get over leaf to a respectable builder, and it comes cheapest in the end.

CAROLIC ACID (H. F. F.).—As your walks have wooden edgings the carolic acid once mixed with one hundred parts of water will not injure the flowers near the edge of the beds.

WHITE TRUMPET LILY (E. G. Z.).—This is probably *Lilium longiflorum sinense*. A portrait and description is in the "Botanical Illustrator," vol. 10. It is a native of Japan. A list of the Lillians is in all the botanical dictionaries.

PRONUNCIATION (Delta).—There is no work devoted to the subject. All botanical dictionaries have the names accented.

VARIEGATED BRUSSELS SPROUTS (W. B. B.).—The specimen sent is the whitest we have ever seen, neither the head nor the side sprouts containing more than a tinge of green. For ordinary purposes we should not regard it as a variety, but as a decoration. The plants are very hardy, and grow with free growth. If healthy it would be conspicuous in shrubby borders. The plant sent appears to be in good health, but perhaps it has been "selected." Give it a further trial in order to prove its constancy and hardiness.

CLIMBER FOR VERANDA (W. P., Edge Hill).—We should plant the *Crimson Bourneville Rose Amadis* on one side, and *Madame d'Arbury* (hybrid climber) on the other, and allow them to intermix. It might be better to veranda the first year, but would do so quickly. Or you may sow *Tropaeolum canariense* and tall *Nasturtium*, which would answer until destroyed by frost.

WINES-FLOWERING CARNATIONS (Wild Rose).—You do not say what varieties are grown, but we presume the Tree Carnations. Young plants after the first year should be struck in gentle heat early in March, close until established, when they should be gradually hardened-off in a cold frame, the points of the cuttings being pinched out. After danger from frost has passed the plants should be placed outdoors on ashes in an open yet sheltered situation, all they require during summer is shifting into larger pots, stopping the shoots, but not later than the beginning of July, and duly attending to water, staking, &c., housing at the close of September; 6 and 7-inch pots are quite large enough for plants the first year. The temperature, if they are to flower during the winter with certainty, should not be less than 50° in the first half, affording plenty of light, and six airings a week, but heat of 10° to 15° or more in bright mild weather. We prefer to have a few plants in 9-inch pots which are grown on the second year the same as the first, but not allowing them to bloom, stopping them until April and not afterwards, regulating the shoots as they grow during the summer. They are peculiarly adapted for giving a fine and early display of color into the blooming pots in June. They will bloom in late summer or autumn, and continue through the winter. The best of the Tree Carnations are Princess Christian, Miss Jullife, La Belle, Princess Beatrice, Zouave, Queen of the Belgians, Marchioness of Westminster, Annie Williams, Empress of Germany, Monsieur Zola, and La Grenadier, and what is the latest named, Pieter de Malmaison, Prince of Orange, and Grandia.

ACHIMENES CULTURE (P. F. S.).—When the plants have grown about an inch above the soil, or between that and 2 inches, they should be lifted carefully, preserving the roots to each, and be planted in pans, commencing at the sides, placing them 2 or 3 inches apart, and six airings a week.

The plants are to be 4 inches in depth and 15 inches in diameter. We drain them about 14 inch deep and place an inch of the roughest of the compost over the drainage. The plants are inserted about an inch deeper than they were before, and we have the soil next the rims of the pans about half an inch below them, and rising slightly to the centre. The plants are grown near the glass in a house or pit having a temperature of 65° to 60° at night, and 70° to 75° by day, with a rise from sun to heat to 80°, admitting air freely and maintaining a moist atmosphere. We top-dress the pans when the plants are a few inches high with rich compost just on the surface, or cow-dung well-decayed, mixed with equal parts of loam and sand, answered well. The compost used consists of equal parts of light turfy loam, sandy peat, and leaf soil, with a half part of old cow dung or well-decayed manure and silver sand, thoroughly mixed but not sifted. Water is applied carefully, not allowing the plants to become very dry, but giving a little water to the roots by top-dressing applications. Some growers stop the plants when 3 or 4 inches high, but instead we put in light green stakes at that time, and endeavour to form the plants by the disposition of the stakes into a half ball, regulating as its growth proceeds, and as they branch from the bottom small shoots are left. For filling in vacant spaces, liquid manure is given, and the plants are watered after the plants are growing freely. When in flower they are the better of slight shade and a lower temperature. There are few finer objects than a well-trained and bloomed pan of these plants.

HARDY ANNUALS FOR POT FLOWERS (John Jones, Sower).—The best six hardy annuals for cutting are Sweet William, *Chrysanthemum carinatum* Donnetti flore-pleno, Sweet Sultan (purple), *Hebeida odorata* var. Queen Victoria, and King of Tom Thumb Scarlet *Nasturtium*. Having no heat no hardy biennials, unless you procure plants, will flower this year. Six are—*Campylosiphium*, *Dialycanthemum*, *Dolicholobum*, *Androsace*, *D. grandiflorum* celestinum, *D. distichum*, and *Androsace* flore-pleno. Scarious double dwarf, and Sweet William, Anriens-eyed (Bragg's). The best six out of the two sections are distinguished by asterisks.

PEAS FOR EXHIBITION (Idem).—In addition to Commander-in-Chief (Carter's), Supplianter (Laxton) is good, being fine pods.

WIREWORK FOR VINE BORDER (E. P., Leicester).—If you are certain that wirework is greatly abused in the soil we advise you to remove it as soon as possible. If you only suspect their presence, or if there are only a few of them in the soil, they will not do serious injury, and you might trap them by burying Potatoes and Carrots, examining them periodically. The best traps

SQUIRRELS—HEDGEHOGS—BULLFINCHES.

I have read with interest the articles of J. Gadd and "AN OLD GARDENING BOY" upon "Squirrels as Depredators" in our Journal of February 22nd, and I have waited to see whether more letters would follow, but as no more have appeared I now claim the right for a reply. My garden friends must allow me to say that all mice, rats, and the most predacious and class dislikes. They do sometimes rise to simple hatreds. The disks of some gardeners to birds and animals may be classed among them.

My aim is truth, apart from sentiment on the one hand and unreasoning destruction on the other; also I am always, I hope, open to conviction. That there must be a balance preserved throughout nature is, I am sure, necessary. In England as to smaller birds that balance has been upset by the destruction of the hawk tribe by gamekeepers. They are the only men who are allowed always to carry a gun. The carrying of swords by gentlemen in the last century had to be put down by law because of the destruction to human life caused by men going about armed, and I wish something of the sort could be done as to the keepers' guns. The men "get out of bed the wrong side," or the chimney smoke, or the village school, or the master is angry, or last night's best lingers in the head; the armed keeper avenges himself by shooting every bird he sees and every squirrel on a beech tree. If every man in England carried every day a loaded gun I believe murders would abound all over the country.

Take now the squirrel. I have lived twenty years with them around me, and have suffered no harm? Why? Because there are millions upon millions of beech nuts in the shrubbery upon which the animals feed. Under quite altered conditions I would not advise the over-preservation of squirrels, though indeed they never abound save where the beech mast is plentiful. Keep a tame squirrel, let him out into your garden where there are no beech trees, and he will find his way to the peaches, &c. I ensure strongly indiscriminate slaughter of that mischievous animal the squirrel. Then I am sure they are constantly blamed by the dishonest. A hedge gardener who was proved to be dishonest, and confessed his dishonesty at last—he was in the habit of sending his master's fruit to the large city near, and being questioned as to the scarcity of the fruit he always pleaded as an excuse the squirrels. Another man, dismissed for the same reason, did the same. Masters and mistresses who read this paper—and many do—I appeal to you against total destruction of squirrels where there is beech mast for them, and where there are no plantations of small firs, the young ends of which I have said they nibble off.

Again I ask that when it is necessary that these animals be destroyed that no traps be used, at least unless they be of a kind to catch them alive and uninjured, when the trap can be plunged into water and animal drowned. It is better, however, to shoot them: a nice occupation for master himself, by the way, who will only kill a limited number, for I have known gardeners who set a gun for shooting waste their time—I mean their master's—hour after hour walking about with a gun. Stopping and working make the back ache, walking with gun on shoulder is no work at all.

I notice in last week's Journal that my words extracted from the French ministerial order are questioned as to harmlessness of hedgehogs. These poor animals have suffered terribly from class hatreds. The cowman declared they sucked the cows—a thing impossible because their mouths were too small, but it was sufficient for a dishonest cowman to make his master believe this nonsense. Then the gardeners in old times used to declare that the hedgehogs rolled themselves on the fruit and walked away with them on their spines; but in truth their spines are so arranged by nature that no fruit will stick on them if the experiment be tried. The poor hedgehog was perfectly free of blame in both cases. Its usual food is beetles, worms, slugs and snails, also frogs, mice, and even snakes. Occasionally it is said to eat eggs, and this is the point urged by "AN OLD SUBSCRIBER." I am surprised to hear, however, that the hedgehog can eat any than a small egg. What, however, is truly said by "AN OLD SUBSCRIBER" of the hedgehog may be said of birds and squirrels, "they require keeping in bounds;" but I think the actual usefulness of the hedgehog very greatly exceeds his powers or habits of injury, and it nowhere is very abundant.

Returning to the squirrel. There was a custom in some parts of England for the riff raff of each village, the idle men and boys, and, worse than either, the hobbdehoyes, to go out in the woods and plantations every St. Andrew's day, November 30th, armed with sticks and weapons to hunt squirrels. A number of these they maimed, bruised, wounded, and killed; but the real object was to prevent the killing of nuts, to pick at or get hold of game and rabbits, to bark hedges and plantations and get firewood. The day ended by a sapper at the public house, at which the game and rabbits were eaten, and the land-

lord benefited much by the quantity of beer drunk. The poor squirrel has had a bad time of it—blamed wrongly, tortured, and put forward as a pestence. Its beauty, grace of limb and action, appealed all in vain to the cruel.

I now turn to the subject of the bullfinch, and I am sorry to say I have not a single good word to say for him. Naturally and untaught he has no song. Unlike the chaffinch or the goldfinch (would that the birdcatchers had not almost exterminated them), or the linnet, he never cheers us with his song—he never makes the garden joyous with music. His habits are shy, and repelling, and unsocial. He lives almost all the year in the woods. His colours are handsome, though rather gaudy perhaps, but his shape is as unpleasing as a bulldog's. He remains far from man's dwelling except in the very early spring or late winter, and he then comes a destroyer. Unfortunately bullfinches are on the increase. They do not pay to catch, for they cannot sing and cannot be taught to sing, except when taken from the nest or in their brown nesting feathers. And then there are no hawks to kill them (oh, those keepers!) So unto our gardens they come in February, and first begin in the Gooseberry buds. In a very few minutes all except on the extreme ends of the shoots are picked out and eaten. Then next they attack currant buds and then the plum buds, and they are eaten—nothing left but little empty cups all up the branches of gooseberry, currant, and plum tree, and so the crop is gone. This mild winter they have been unusually destructive to the gardens around; rather strange that the other berries of the hedges. I must pronounce a sentence of death upon the bullfinch. I hold not to sentiment but reason. Apparently little care was taken to provide this mild winter against the depredations of the bullfinch, and hence most gardens have suffered.

The best plan in regard to gooseberry bushes, especially those of upright growth (with which only the plan can be well carried out), is early in the winter to tie them close up with a withy or a bit of wild clematis or tar string; bend their branches together in a mass; and though the birds will eat the outer buds they cannot get in to eat the inner. When the leaflets come out untie the trees, for it is only the buds as buds that are cared for. Another plan is to get some balls of the thin twine—a loose, very thin, flossy, yet strong string used by saddlers (it is very cheap), catch it on the branches, crossing and recrossing. Mr. Bully thinks it a net, and, like all thieves, objects to be caught. White-wash, too, they do not like. Shavings and little flying flags or paper Mr. Bully is up to. They might have frightened his great-great-great-great-grandmother when she was young, but these are days of enlightenment and school boards. Bullfinches must be shot down or killed in some humane manner, they are no good, they do only harm. I am sorry to have to write this, but a useless thief, though he wears a velvet cap and a red waistcoat, must be got rid of. Germany will always supply us with the best piping birds, and in her forests the stock of birds is inexhaustible, and a good trade is made by the German bird-traders.

In conclusion I would say, Do not allow the squirrel to be exterminated, but keep him where his natural supply of food is provided. Do not exterminate the hedgehog, for his usefulness is greater than his power of injury. But do if you can thin-down with no sparing hand the Bullfinch, for he is only to a degree ornamental; he is not useful, and is a very injurious bird.—WILTSHIRE RECTOR.

THE CRYSTAL PALACE BIRD SHOW.

(Continued.)

The awards in the four Lizard classes were disposed of to birds of Gold and Silver-spangled stamp, pure and simple, without any regard being paid to the pedantic and fatuous notions of "pencilled" or "semi-pencilled" birds. To attempt to establish classes for Lizards otherwise than "spangled" birds would be an attempt at hair-splitting, anything but wise and advantageous to the Lizard Canary fancy. The idea, evidently, is a *fool* one, and about on a par with that which occurred some years ago when an attempt was made to introduce "blue" Lizards, which are as unlikely as a blue dahlia. It is a treat to us, and one we never become satiated with, looking (not in the way of a mere glance) at the Lizards. Class 20 commenced the lot, and we could not think otherwise than that the first prize bird (630, Ritchie) was a bouncing specimen in all points—a decided win over the others in the class. The competition rested now with Nos. 616, second (Salt); 629, third (Reid); and 627, fourth (Reid). No. 633 (Fairbrass) would have led forward place, to judge from appearance, but the foul feather which did appear in the shoulders, and which must have been the means of lowering its flag. The class numbered twenty-six, and was a tolerably good one, excepting here and there of a bird or two being poor. Of the two dozen Silvers Mr. Bunting landed a clever first in fine condition, a decided win, although it must have run a dogged race with Mr. Fairbrass's second (658), Mr. Salt's third, and Mr. Ritchie's equal

third, betwixt which there was not much choice for places. In Classes 22 and 23 Mr. Fairbrass was cock of the walk, taking first in "broken" Golden, and first, second, extra second, and third in "broken" Silver, the other prizes being disposed of to Mr. Salt's 685 (second), which we thought good enough for a first; and Mr. Russell's 687 (third), cheaply sold for £15. 15s., although there were other birds in the class we preferred. Sixty-three Yorkshires were entered, of which number Mr. Thackrey was the winner of three firsts, two seconds, and two thirds out of his twenty-three entered, whilst Messrs. Wilkinson and Holroyd won a first and second, and Mr. Belk a couple of thirds, all fine birds of their respective breeds. In the high-coloured Cinnamon Mr. Pope of Brighton must have felt happy in winning first in Yellow and first in Buff with two such splendid birds, which, we believe, were quickly claimed at £2 12s. 6d. each by Messrs. J. & W. Waller of Finsbury, the noted breeders of the London Fancy and Cinnamon birds. Although the noted Coventry breeder of Cinnamons (Adams) was knocked back a peg, still his Buffs were all there for colour, quality, and condition, and were awarded second, third, and extra third. We must not omit mentioning Mr. Munnes' second Yellow, Mr. Athersnot's third (another noted Coventry breeder and exhibitor), and Mr. Pope's extra third. Mr. Salt's (794) extra second and Mr. Caplin's (806) third prize both did credit to their respective owners. The Cinnamon (not of high colour) in the next two classes bore a more modest appearance compared to their high-coloured compeers in the previous two classes, and were to make choice of birds for breeding purposes we would rather choose those not peppered. Class 30 commenced the Yellows, and Mackley Bros., who headed the list, chalked first and third, Mr. Irons of Northampton being second with a fine-feathered bird. We are always pleased to hear of new exhibitors entering the competing arena, and we were such in the case with Mr. Kinderman of Putney, who won first honours in Class 31 with a fair bird, exceeding cheap at the catalogue price of £1, although we preferred Mr. Smith's second-prize bird.

Time pressing somewhat close upon us, and having a wish to devote a little attention to the Mules, we passed hurriedly over Classes 32 and 33, both numerously represented with birds of a varied kind. We could not help noticing that in the latter class there were birds present which had no claim to a position, owing to the stipulation that the class was "for other varieties of Canary not previously specified." This was not adhered to; but we are not going to condemn entry 912, which stated the bird to be "twice crossed, three-quarter London Fancy and remainder Lizard!" A little of the Darwinian study here evidently. After leaving cage 922, a "wild Canary from St. Helena, a capital songster" (no doubt in our absence)—we came into immediate contact with the Mules. We were not carried away with surprise with the eleven entries in Class 34, Evenly-marked Yellow Goldfinch Mule. Mr. Doel of Plymouth headed the class—his old place—the first-prize ticket being attached to cage 923, containing a seven-months-old bird, valued at £100! We have seen better Yellows shown by Mr. Doel, notably a couple of beauties about five years back. As to condition the bird was all there, and was well backed-up with two other specimens for second and extra third places. Mr. G. Russell's equal second was sent in exhibition form, and Mr. Salt's third Yellow would have shown to greater advantage had it been in better condition. Mr. John Brown, a well known Mule exhibitor hailing from Penrith, gained a very deserving extra third prize with a good-conditioned bird. The Even-marked Buff class contained seventeen entries, the first-prize bird, exhibited by Mr. Doel, being the very best Even-marked Buff we ever saw, and that is saying a great deal. Its general style, condition, and plumage was really superb. The same exhibitor also took second and third with birds in the pink of condition and plumage. Two equal seconds were awarded, one to Mr. Steven's bird, No. 946, a fine six-marked specimen, which, however, had one dark feather, the side of its tail slightly broken; the other to Mr. Salt's 941, which at first sight appeared very attractive, but which had a feather in its right wing misplaced, and appeared somewhat discoloured for the dark feathers up the left shoulder. 939 (Salt), a fair bird, lacking somewhat in dash and general style. The class, however, was one of the best in the show. Classes 36 (Unevenly-marked Yellow) and 37 (Unevenly-marked Buff) were fairly represented, the latter especially with twenty-nine birds. Here again Mr. Doel was the chief winner, taking first, second, and third honours with extra showy Yellows, Mr. Russell again coming in for a very capital extra second, and Mr. Willsher for an extra third. In the Buffs out of seven Mules exhibited Mr. Doel gained the premier place besides second, third, and an extra third, three others being very highly commended. An extra second was also given to a splendid bird belonging to Mr. Salt, and a similar mark of distinction to Mr. Luke Belk's bird. Two special prizes were given to the class to two beautiful Mules full of quality, which, no doubt were worthy of the prizes considering that the breeding of such choice specimens are of so rare an occurrence, the owners of the birds being Mr. C. J.

Salt, Burton, and Mr. Brown, Penrith. Classes 38 and 39, Dark Mules, Yellow.—Mr. Salt was the winner of the three prizes, whilst Mr. Bexon was awarded first position in Buffs, a mistake certainly, the second-prize bird belonging to Messrs. Cox and Griffin being vastly superior. Classes 40 and 41.—The prizes in the former, as usual, were disposed of thus: first and third to Mr. Stevens, and second to Mr. Spence, both noted north-of-England exhibitors. Of their kind the birds were particularly choice. In the latter class (Dark Linnet Mules) the north again triumphed over other parts, Mr. Tenniswood of Middlesbrough being first and Mr. Stevens of the same town second. There were some very good cages of six in Norwich, Lizards, and Mules, the chief prizetakers being Messrs. Mackley Bros., Fairbrass, and J. A. Sleep of London. The Lancashire Copy and Plain-head class filled very well, but several of the entries failed to put in appearance, owing to some unfortunate mistake occurring in the non-delivery of the labels, which we were assured were posted at the same time as others. Mackley Bros., Wright & Smethurst, Salt, and Thackrey were the prizewinners. Class 47, Scotch Fancy, numbered fourteen entries, which was good considering the distance for the birds to travel. The first prize was won by Mr. Thorpe, Dumfriess; second by Mr. Thirkettle, Norwich; and third by Mr. Mauchan, Dumbarton.—A VISITOR TO THE SHOW.

APIARIAN OUTLOOK.

No more promising season than the present for poplons hives and early and strong swarms has been known in our part of the country for many years. Spring is upon us in the middle of February. A week ago I gathered a blackthorn blossom, and saw laurels in full bloom besides hosts of spring flowers of many varieties. Never have I known such a splendid bloom of laurustinus, scenting the air far and near with its peculiar fragrance, while a hedge of Berberis Darwinii has been out in blossom for some time, and its sister Berberis of Japan is overblown, and B. aquifolia fast developing. Meanwhile my hives have been hard at work pollen-gathering for full a fortnight, with a rapidly rising temperature. Not only so, fresh gathered honey is seen in two or three hives glistening—a cheering sight to the beeowner. I presume it must be gathered from the laurustinus, of which we have a large quantity, while other flowers are now scarce in like abundance, not even the golden rod, from which bees gather such quantities of pollen, and their richest honey supplies in most springs, although I see its cheerful golden cups peering out of the grass in all directions.

What is to happen no one can tell, but it seems hardly probable we can see winter again with frost or snow, although a long continuance of northern and eastern blasts is fairly due to us. Nor is an early spring necessarily followed by an abundant honey harvest. Still there is good hope, and I now write to encourage all our apiarian friends to spare no pains to give their bees every chance and opportunity of success.

It is, bear in mind, of the first importance to encourage the growth of a large population. To this end three things are of essential importance—warmth, food, and breeding space. To these must be added shelter from the driving winds. Wrap-up well; supply diligently a gentle and continuous administration of syrup with a dash of brandy in it; enlarge the entrance, but very gradually, and only as such enlarged room for exit is required; and do not fail to increase the breeding space in your hives by adding ekes as time goes on. These can be removed in the autumn after the honey season is over, and the hives reduced in dimensions for the winter; but in April and May every encouragement should be given the queen to lay, and the bees to rear the largest possible quantity of brood. Swarming, perhaps, will be delayed a week or two, but the swarms will be larger and the honey harvest greatly increased as well in the swarms as in the parent hives. Simultaneously, too, with the increase of space by means of ekes below, supers above the hives should be given as the population grows and the weather improves. If this is carefully and judiciously done there will be little complaint of the queens breeding in the supers. They do so simply because they are cramped and confined below.

I am not an advocate for wintering bees in large hives. They suffer more from cold, while they are not exempt from illness common to bees, such even as dysentery; but by all means let them be as expansive in spring and summer time as the need of the bees requires. The ekes added below should be from 2 to 3 or 4 inches deep, of straw or wood according to the pleasure of the bee-keeper. A second may be added as the first is filled. Comb-making will commence downwards by elongation of the overhauling combs, as early and as rapidly as the strength of the population permits and the exigencies of the queen demand. Perhaps the beginning of April is soon enough to commence eking ordinary hives in ordinary years. Exceptional cases of season and strength of stock will be met at the bee-master's discretion.

As to feeding, there may be instances of poorly supplied hives; if so, they ought to be fed more liberally henceforth

for the amount of food consumed while breeding is going on and as the population increases is enormous; and although honey is collected from the early spring flowers in considerable quantities, there will often be weeks during the prevalence of dry parching winds when nothing will be gathered. Therefore, let every bee-keeper be careful to watch his hives and test the amount of food stored-up within each stock as he shall be able to do so. Here it is that the common straw hives are so defective. No one can tell properly their condition, as it is impossible to see anything of their stores. Nor will weighing the hives be of much use, for the young brood in the cells is often very heavy.

Mr. Pettigrew's advice in a recent number of this Journal (page 130), is worth attending to. I am happy to be able to endorse it to the full.—B. & W.

DO BEES EAT POLLEN?

WHILE on a visit to an enthusiastic apiarian a short time ago he took at his beehouse some modern works on bees for me to look at. On opening Mr. Frank Cheshire's little work the following sentence met my eye:—"Mr. Pettigrew, whose practice is more accurate than his philosophy, tells us that 'bees do not eat pollen; they die of starvation with a superabundance of it in their hives.'" "But the latter fact," says Mr. Cheshire, "does not prove the former. A man would die of starvation if fed only on Liebig's extract of meat on the one hand, or on sarracenia on the other; but by uniting the two he has a sufficient diet. So with the bee. With pollen only they would quickly die of cold; with honey alone tissue is soon exhausted, and vital energy slowly but surely extinguished." The physiologist perfectly understands this matter, and has shown by analysis that a true proportion of the essential food of animals—flesh and heat forms—is necessary, in order that the largest results may be obtained by any given consumption of them." (page 61.)

It will be observed that Mr. Cheshire has not attempted to support his statement by the evidence of facts. His reference to the well-known physiological fact that heat and flesh are produced in animals from different principles, does not prove that honey does not contain everything necessary for the health of bees. We know that bees can work well and live a long time without pollen. At the present time I have twenty-two hives, strong in bees and healthy in every respect, that have not a particle of pollen in them, and not a bee in these twenty-two hives has tasted pollen for the last three or four months. Mr. Cheshire may wish to build up a verbal argument on this point, but they will not outweigh this simple single fact. "Accurate philosophy" is generally on the side of facts; and this I believe Mr. Cheshire will readily admit, for he is an honest writer and means well.

Swarms, on being placed in empty hives, do not gather pollen for some time, though they work hard. In about three days of fine weather, or when some combs are formed, a few bees begin to carry in pollen, which, I believe, is used for nursing purposes only. Bee-bread (or pollen) and water are used in rearing brood, but I have never known adult bees use them on their own tables. I am not aware that anybody can prove that bees eat pollen. Many a time have I given bees honey slightly mixed with pollen; they invariably took the honey and left the pollen in the vessels. Bees have the power of straining or filtering out pure honey from a nasty mixture of honey and pollen. I have referred to twenty-two hives in my garden which have not a particle of pollen in them. I could undertake to put one or more of these hives into a dark cellar, and there keep the bees in perfect health and strength on either honey or sugar-syrup alone till they die of old age. I hold that honey and sugar contain both the heating and flesh-sustaining elements, and that pollen is not eaten by bees or necessary for their health. No man is better able to place his experience before us in an intelligible form than Mr. Frank Cheshire, and if he possesses facts on the question disputed, and is thus able to establish the "accuracy of his philosophy," no one will be more pleased to see them than his sincere friend.—A. PETTGREW.

STEWARTON VERSUS STRAW HIVES.

Your correspondent "W. J. C." asks "How are we to understand that the Stewarton stock was in such excellent condition, while that of the straw skep was at starvation point?" I reply, It is very easily understood when it is taken into account that the Stewarton was the best kind of hive, offering greater facilities for its intended purpose and for storing honey than the straw. In Mr. Lowe's succeeding contribution he used the information I had furnished him and "W. J. C." against me, that the two hives were not on a par to effect equal results, forgetting all the while he was handling a two-edged sword. If they were so, where was his equality theory? I can assure "W. J. C." he will find it much more difficult to understand that all kinds of hives, whatever be their "form, material, and construction," occupy a perfect equality or common level than he will that

the Stewarton is superior to the straw. He never will find perfect equality of results from a variety of bee domiciles, although he search for it, as he did in his last letter, even up a chimney flue. One chimney over another may be so constructed as to possess a greater back-draught and effect the result as to quantity, and deteriorate the quality by sooting in proportion.

"W. J. C." uses a rather strong expression as to my competitive test hives, that after "being greatly puzzled by your correspondent's statement. . . . I cannot see it possible." To this it is replied I only stated facts. The honey harvest from both stocks was carefully weighed to an ounce; the condition of both after being witnessed was substantiated by two most experienced and credible witnesses, and I fail to perceive that the admission of facts is to be held responsible to reconcile such with the notions of every reader.

"W. J. C." further says, "Your correspondent seems singularly unfortunate in the shape and working of his skeps. . . . and that too in a very bungling manner." Before these lines appear in print his mind will probably be relieved to find the competitive straw has found its proper level and is otherwise peopled. Instead of that straw being wrought in a "bungling manner," it was far the best-managed stock in my apiary. The clear proof of this was the thoroughness with which the honey was diverted to the glass, and the weight and beauty of that glass placed it above its competitors.

This correspondent narrows some particulars of a visit he paid to the late Mr. Woodbury, and reports the gist of a conversation that passed between them, which I must confess both puzzled and surprised me as well as many a reader. Although I never had the good fortune to meet that gentleman, yet he corresponded very frequently for several years. Every letter he wrote me I have carefully preserved; he presented me with a copy of his treatise, "Bees and Bee-keeping," consequently the great apiarian "being dead yet speaketh." It would therefore be deeply interesting to the present writer as well as every British bee-keeper could your correspondent fix the date of his visit to Mount Radford, so as to place on record the time our respected chief changed his opinion as to his much-prized Italians. If early, as the price of the stock would indicate, then I think it can be easily shown he very materially changed his view as to the value of the yellow-jacket. Our respected father, like all of us who sit at the feet of that good dame Experience, never adopted "fixity" as a part of his creed.

As mentioned above, it is at all times most interesting to the bee-keeper the many odd cronies our little favourites take up their quarters in, not so much so, I daresay, from choice as necessity, when overlooked at swarming time by careless owners. In Bible lands "honey from the rock" is the rule, we have the "bee tree" of America, and the still commoner roof colonies of our own country. The first stock the writer could claim as his very own he found well combed, quite open, on the under side of a branch of an Ash tree, and the clergyman's lady referred to in remarks on "Grude Honey" only experience as a bee-mistress was with a stock she discovered ensconced in a high wooden-covered pen well placed in a raised corner of her manse garden.—A. RENFREW'S BEE-KEEPER.

[We can only spare space for facts and fair arguments.—Eds.]

HIVES.

It is astonishing how much is expected of our little friend the busy bee. The people who begin bee-keeping and throw it up in disgust after a year or two's experience are very many, for the simple reason that they think it only necessary to obtain the bees and honey, and increase must of necessity follow without any further trouble. This idea is not confined to the uneducated. Many instances have come to my knowledge where ladies and gentlemen of position, who have in the first instance spared no expense in hives and bees, have yet failed to see the necessity of a little after-attention; indeed, oftentimes they have been too timid to touch the bees or remove the crownboard of the hive. With such people frame hives, sectional supers, and extractors are quite thrown away, and straw skeps are the only hives they are equal to manage.

Then, again, many persons who are successful enough to derive a moderate profit from their bees are discontented because they cannot obtain supers approaching the size and quality exhibited at our shows, forgetting that these are generally very exceptional results, seldom obtained without the expenditure of great care and skillful management. A man may keep bees for years, manage them well, and yet not obtain a super of 80 lbs. or 100 lbs., or such a harvest from one hive as recorded by "A RENFREW'S BEE-KEEPER." It is true I could name perhaps half a dozen gentlemen who are almost sure to come to the front with prize supers. This may partly be ascribed to locality and skill. Huge supers I have long ago discovered and pronounced a mistake. It is true, if perfectly full and all the dangers of transit to the show are safely passed, a prize may be won, but the winning super is unsalable. No private person wants to

buy 100 lbs. of honeycomb, and no dealer cares to "cut and come again" at such an endless messy job. The smaller the super the more easy is it to sell, and hence the great value of sectional supers which I have and believe will soon come into general use. Each section should not cost more than 2d. if bought, and need not cost 1d. if home-made. At those prices the super can be given or sold with the honey, as is a tin canister with many of our grocery stores. The prices I have named are not imaginary, for sectional supers as good as can be desired are actually made and sold by one of our best hive makers at 2s. 6d. the set of sixteen. Clean delicate honeycomb in the houses of the wealthy is appreciated as a breakfast luxury, and one of these little supers can be consumed while fresh, whereas a very large one becomes nauseating by its repeated appearance.

I am glad to see our old contributor, "A RENFREWSHIRE BEE KEEPER," once more to the front as a frequent correspondent of the Journal, and greatly admire his gallant advocacy of his favourite system, the Stewarton. I cordially agree with him that the test, *skip versus frame*, was fairly conducted, and as fairly won by the frame; but I cannot help thinking that had our friend bestowed equal care and skill on a Woodbury hive the result would have been a little different; I mean the result was arrived at not by any particular charm of the Stewarton system, but by the greater facilities afforded by a frame hive with means of expansion against a closed straw skip.

I have not entered into the renewed "battle of the hives," as I think enough has been said. The only two charges that have been retained against frame hives are—first the expense, and secondly the damp internally. The latter is remedied by proper ventilation; the former does not exist. It is true that in frame hives there is more scope to spend money. One man will not object to pay guineas, while another will look twice before he parts with his shillings, and the latter man with good management will obtain a hive for his smaller coin capable of affording the bees equal facilities for the storage of their harvest as the most expensive. In like manner busy brains have invented scores of appliances more or less handy to the bee-master; but very few of these are necessities—merely luxuries, such as we can either make or do without. A handy man who can use a hammer, plane, and saw may make a serviceable two-story hive with legs and roof for 5s. or 6s., less than half this if he has the wood. I have several hives in use, the result of a morning's work and the materials of an old wine case. Doubtless a carpenter would laugh at my work, but the bees don't. I know from the many letters I receive that there is many a working man would like to start a frame hive if he knew how or had the means; to such let the above be encouragement. —JOHN HICETER.

The unusual warmth on the 10th of February tempted me for the first time since October to overhaul one of my Stewarton hives. The family consisted of two lots of black bees, which were driven out of straw skeps last autumn and were subsequently supplied with an imported Italian queen. I found the interior of the hive in excellent condition, free from the slightest trace of damp, and the queen apparently in good laying order. The three central combs contained a considerable quantity of sealed and unsealed brood, and recently hatched bees were running over the combs, clearly proving that breeding had been going on in January.

In reply to some observations by Mr. Pottigrew upon the subject of ventilation I may remark that I have found the quilt, when properly used, a perfect remedy against internal moisture, and, after employing wooden and straw frame hives for many years side by side, have not found the latter possess any advantage over the former on the score of dryness.

To prepare my Stewartons for their winter campaign I remove all the slides, and insert the little plugs or stops between the ends of the bars. A piece of Brussels carpet cut to fit the top of the hive is then carefully drawn over the bars and secured in its position by a few small tacks. No hammer is requisite, as the tacks are easily pressed down into the soft wood with the handle of a trowel or any piece of hard wood with very little disturbance to the bees. Two or three pieces of old carpet or flannel are then laid over the wire, large enough to overlap 3 or 4 inches on either side and tacked down between the hive and its exterior cover. My hives are all in the open garden, each upon a separate stand, protected from the weather by a loose outer cover with a sloping roof. As the roof is loose with plenty of space between it and the top of the hive, and as there is an interval of an inch on all sides between the cover and the hive, perfect external ventilation is secured, and any vapour arising from the interior is at once carried off into the open air without condensation; in fact the interior of the hive is well aired and kept dry by the bees. In proof of this the iron tacks (not tinned) which have secured the pieces of carpet over my hives since October are still perfectly clean and free from rust. —J. E. BAISCOE, Abington, Wolverhampton.

OUR LETTER BOX.

CHEEKERS STAGGERING (S. C. James).—They are over-fed. There is a pressure of blood on the brain.

FEEDING FOWLS (E. C. N.).—The ground food is more nourishing than whole corn. If you want a proof of it you will find that while a bird fed on ground food will put on fat daily, one fed on whole corn will alter very little in condition. The support you speak of is not required during the night. The bird is entirely at rest, and there is no demand either on its strength or digestive powers. If there were we should think we were enabling the bird to meet it more effectually by giving ground than by giving whole corn. We do not like your feeding, and fancy you will have fowls dying of fat. All the subtleties for natural feeding are mistakes, and most of them lay the foundation of disease. We keep thousands and have done so for years, and after trying all description of food are so satisfied that we have chosen the right and proper method, that if anyone would give us any other food we would not accept it. Barleycorn or ground oats morning and evening, corn at mid-day, or any other food, such as kitchen-waste, whole maize or barley. We have always found ground maize to be unappetising to fowls, but when they took to it they put on fat very quickly and to an injurious extent. Ground buckwheat is also very fattening and unfit for feeding. Wheat flour is also a bad thing. Your birds are laying very well. You will probably have plenty of broody hens before long. We advise you strongly to alter your dietary for our plain living. Do not overfeed; you will save in every way by being moderate. Half the fowls are spoiled by overfeeding, and nothing tends more than that to give a fixed quantity of food. Feed them as long as they will run after it and no longer.

BOOK ON BEES (Neophyte).—We do not think you will find a book better suited for your purpose than our "Bee-keeping for the Many" which you can procure from this office for 5d. by post. Perhaps "Profitable Bee-keeping" would meet your wishes, by the Rev. F. V. M. Pilleul, price 6d., which you can procure of any bookseller. It is published by the Society for Promoting Christian Knowledge. Feed now. Let the sun shine on the hives now, but not in summer.

BEES DEAD IN THE COME (W. F. Mulcaster).—No inexperienced person could see the dead bees in the cells as yours are without fearing that they would vitiate the combs and be hurtful for a fresh swarm introduced to them. On the confines of starvation bees naturally give the last sip of honey to their queen, and then bury themselves 3-diply in the empty cells of their combs. In this way they seal their own fate, and the queen, if the hive has been kept dry since the death of the bees they will be easily removed by a fresh swarm and cast out of the hive, or you may remove the greater part of them by a knitting needle. If the combs are otherwise clean and good you have nothing to fear.

REMARKS.

- 7th.—Snow and rain in early morning, gone by 9 A.M.; snow and bright sunlight at 10.30, frequent heavily in the afternoon, and with high wind at night.
- 8th.—Very dry and cold; frequent snow showers during the day, bright sunshine often following them; the flakes were very large and numerous, but it melted almost as soon as it fell.
- 9th.—Rather foggy day, but very cold all day.
- 10th.—Dull and cold, but quite fair at times, bright, but very cold.
- 11th.—Fair all day; but rather dull and very cold.
- 12th.—Damp morning; a fair but not bright day; much warmer, especially towards night.
- 13th.—Fine morning, but soon becoming dull, and then showery.
- Sharp frost on 11th and 12th, rendering the mean temperature rather lower than that of the previous week. Each of the last four weeks has been colder than its predecessor.—G. J. SYMONS.

COVENT GARDEN MARKET.—March 14.

A few good samples of Strawberries have reached us, but trade being quiet they are not reaching as much as they have done, and according to present appearances a good many may be shortly expected. Good late Grapes are coming forth and making good prices. Trade still quiet.

From observations taken near London during forty-three years, the average day temperature of the week is 51.2°; and its night temperature 33.3°.

PRUNING AND TRAINING PLUM TREES.

OUR answer to a correspondent concerning a Plum tree reminds me that we do not often see this fruit well managed on walls where there is anything like system in training; but, on the other hand, where a tree is allowed to grow in a half-wild state by a cottage we may see fruit of medium quality produced year after year in abundance. Why is this? and is there no way of producing fruit except by following the cottagers' system?

The cottage undoubtedly has some natural advantages; its walls are warmer. A wall of any building, even if unheated, must always be warmer in winter and spring than a single garden wall, from the fact of its having a body of comparatively dry air behind it. The cottage in addition often has a projecting roof, and this, especially if thatched, is almost a perfect protector. Then, again, bullfinches do not trouble cottage walls seriously, because the birds would not be left undisturbed for any length of time; while here and in many other places they often take every unprotected fruit bud. This is part of the reason why the half-wild tree against a cottage wall produces the most abundant crops; but the other and most important part is that the mode of bearing of the Plum is not sufficiently taken into account when pruning and training are being performed, it being in this respect altogether different from the Peach or Cherry, both of which can be kept in perfect order without allowing the growth to project any further from the wall than the fruit does. But if you would have Plums in abundance you must have spurs on the trees to bear them. True, you may have a few fruits on the best-matured parts of the one-year-old wood, though not often what could be called a crop; but well-grown and matured one-year-old wood, if nailed-in to the wall and treated liberally, will seldom fail to produce abundance of fruit spurs for the following season. Spurs will of course increase in length every season; for to keep them fruitful they must generally be pruned to a wood bud, and they become offensive to the eye of the "neat" gardener, who unmercifully slashes them off without making any provision for a succession. He then wonders why his trees do not bear, and finally blames soil, situation, or anything except himself.

Now, most employers like neatness, but all like fruit, and the taste for the former carried to the extreme will often cause the latter to be a blank. Fortunately there is a happy medium which will please both the eye and the palate. Spurs and branches which have become unsightly may always with perfect impunity be cut off in August or September when there are other branches and spurs to replace them, so long as too much is not done in one season; the wounds will then heal before the tree ceases growth—an all-important point in fruit-tree culture when severe amputations have to be made.

But to begin with young trees as received from the nursery. Whatever question there may be about train-

ing other kinds of trees there is none, in my mind, about the Plum, no other mode will bear comparison with fan training. Trees as received from the nursery have from six to twelve shoots, which should be trained in equal numbers and at corresponding angles to form main branches on each side of the tree. This is the general practice, and it is a good one; but another general practice is to shorten these shoots back pretty hard, and this is not so good. If the points are soft and sappy they should be cut back to the ripe wood, and then the whole of them regulated as to length, leaving when possible the lowest branches the longest, as they have a disadvantage when competing with others more or less vertically disposed.

A little disbudbing will be necessary the first season or two. Growths will be produced on the side next the wall, which should always be carefully picked off, as well as others which are inconveniently placed; but an endeavour should be made to keep the wood covered fairly with foliage, and to attain this end growths may be often pinched back and kept as spurs when there is no room to treat them otherwise. Young growths must be laid-in every season, and some of the weakest and worst of the older shoots cut out as soon as the wall becomes fairly covered, when spurs and fruit buds will follow as a matter of course.

Our trees after they are pruned in autumn receive a dressing of limewash, with which is mixed a good quantity of soot while it is being slaked. Bullfinches do not mind the lime alone when they are used to it; but they are not partial to soot.—WILLIAM TAYLOR.

SEDUM SPECTABILE.

Now that hardy border flowers are receiving more attention than formerly, I am glad to find the above valuable plant is not overlooked. Mr. Record could not have directed attention to a plant more worthy of increase and cultivation, nor have detailed his mode of culture at a more seasonable time. I am not aware that any better mode of propagation can be advanced than that described by Mr. Record on page 198; therefore in these supplementary notes I will confine my remarks to the after-cultivation of the plant, and its adaptability to various modes of decoration.

If a Chrysanthemum is planted in a border and left undisturbed year after year it will naturally produce a multiplicity of growths and proportionally small flowers; whereas if the growths are thinned the flowers are fewer and finer; and better still, if the more robust shoots are struck and grown throughout the season in rich soil magnificent exhibition blooms are the result. In that case the power of good cultivation is forcibly exemplified; but equally striking—even more so—is the improvement resulting from intelligent and generous cultivation when applied to this Sedum. Plants which are established in borders are now pushing a large number of succulent pale green shoots: these if suffered to remain will produce puny heads of flowers of 1 to 2 inches in diameter;

if the shoots are thinned and manure is applied to the plants the flower heads will increase to 4 or 6 inches in diameter; but if the stoutest of the shoots are struck and the plants are grown thinly in rich soil, heads of flowers are produced not less than a foot to 18 inches across. It is when thus grown that the plants are so attractive.

They are effective as bedding plants for massing; as border plants for associating in mixture with other flowers; as shrubby plants for planting in lines and spaces at the front of evergreens; and as pot plants for vases, balconies, terraces, and even conservatory decoration.

As bedding plants I have never seen them grown so well or produce such an imposing effect as in the ideal garden of Drumlanrig. In that grand garden where all flowers are grown by a master in the art of cultivation none are grown finer than this *Sedum*, and no beds command more attention than those occupied wholly with this fine old hardy herbaceous plant. The surfaces of large beds as I have seen them were as level as the smoothest lawn—a sea of rosy pink without a ripple. Anyone may have beds similarly fine by adopting the same mode of culture—namely, young plants thinly planted and strongly grown in rich soil. Such plants are also valuable for mixed beds, borders, or shrubberies, and transplant freely at almost any time during the growing season—even “on a pinch” when the flowers are expanding.

At another place in the north—Archerfield—plants are grown in great excellence in pots for placing on balconies and other exposed positions. Plants in 8 and 10-inch pots with as many heads of rosy flowers are well worth the trouble of producing, and will resist the effects of sun, rain, or wind better than most plants. When thus grown the shoots require to be thinned-out, and the soil strong and rich, manure water being applied freely, the pots being plunged in an open place after the manner of growing *Chrysanthemums*. The *Sedums* require staking, so as to afford room for the expansion of the heads and to prevent them being broken by their weight during boisterous weather. Smaller plants in 5-inch pots are useful for plunging in vases and for furnishing ornamental groups in corridors or other drabty positions; also for window-sills and similar exposed places—in fact, as Mr. Record remarked, these plants “can hardly be put out of place.”

By potting a few plants early and growing them under glass they flower several weeks earlier than their natural season, which is August, September, and October. They are valuable conservatory plants at any season when well grown. Being succulent in their nature copious supplies of water are necessary to bring them to perfection.

S. spectabile variegatum is one of the most charming hardy “foliage” plants we possess, and it is worthy of a place in all gardens and greenhouses. It is constant in its variegation, and always attracts when seen in good condition.

S. spectabile purpureum has darker flowers than the species (*Fabrisia* syn. *spectabile*) and flowers somewhat later, and is a plant worth cultivating; and *S. atro-purpureum* is distinct, also attractive, by its very dark foliage and fine corymbs of purplish flowers; this and the variegated types grown together afford a fine contrast. As generally seen these *Sedums* are half-starved: cultivate them and they will amply reward by their massive heads of chastely-tinted flowers—striking without being gaudy, massive without being coarse.—J. S. P., North Britain.

A SUCCESSION OF VEGETABLES.

GREAT attention is often paid to keeping up a long succession of Grapes, Peaches, and other fruits under glass, and it is considered to be a matter of no ordinary importance to have Grapes “all the year round;” but I consider it is quite as creditable to have a good supply of vegetables of different sorts all the year round. This does not always have the attention it deserves, and even in large gardens there is often a glut of vegetables at one time and a scarcity at another. This is the result, to a great extent, of making too large a sowing and planting of a crop at one time. I have been rather fortunate in securing a lengthy succession of vegetables, which I attribute to attention in sowing the seed, and also in selecting sorts for succession.

No better time than the present could be chosen to begin arranging for a succession of vegetables all the year round. Beetroot, Parsnips, Carrots, Salsify, Scorzoneria, and Leeks need only be sown once, and these crops cannot be sown too soon now. Onions may be sown now, and again during the

last week in August or first week in September. Peas in November, the end of February, and at intervals during the next four months; French Beans, which may be sown in the open ground during April, May, June, July, and August, and under glass the remainder of the year. It is chiefly amongst Greens and salads that the easiest successions are to be found. Cabbage must be sown the first week in August, early in March, and in April and May; Cauliflower must be sown at the end of August, early in February, and at monthly intervals until July; Broccoli, which supplies the connecting all-the-year-round link with Cauliflower, must be sown during March, April, and May; Brussels Sprouts and Savoys may be sown at the same time; Parsley in March and June; Turnips from March until the end of July, when the winter crop is sown; Asparagus, Rhubarb, and Sea-kale in March; Celery in heat in March, and again in April; Cos Lettuce should be sown for summer use in March, April, May, June, and July; and the Cabbage sorts in August and September for winter and spring use; Endive from April to August. Radishes may be sown once a month all throughout the year, but in the winter time they must have the protection of a frame. The same remarks apply to Mustard and Cress. The quantity of every vegetable sown must be regulated by the demand, but whether that be large or small a sowing of everything in its season should be made every twelve or fifteen days.—A KITCHEN GARDENER.

FUCHSIA CULTURE.

FEW plants can equal Fuchsias for profusion of bloom when well grown, and few plants are easier to cultivate; still one often meets with plants falling somewhat short of that gracefulness of habit and abundance of bloom which ought to characterise a well-grown specimen. Fuchsias, like Radishes, are the better for being grown quickly, and without any extraordinary effort plants 3 feet high and as many through can be grown in one season.

Cuttings procured now, if short and strong, will soon strike in a close genial heat. The young growths should be taken off from 1 to 2 inches long and inserted in pots in which a large proportion of silver sand has been incorporated with the soil. These if placed in a propagating case or warm frame (such as a Cucumber bed at work) will root very readily, and in about a fortnight they may be potted-off into 60's, returning them to the frame again for a time, when they will soon require a second shift. This being done and the plants growing well it is time to consider about the training, some sorts forming an agreeable pyramidal shape without much stopping, while others are stronger growers and require stopping frequently to bring them into the desired shape. A pyramidal shape supported with one stout stick in the centre has the most natural appearance, though I have seen and grown them in a bush-like form; but bushes lack the gracefulness of perfectly symmetrical pyramids, the blooms hanging down over the pots so as to almost cover them.

At their second shift the plants will require to have short stakes placed to support and train the leader to, and should side shoots not form freely the leader should be stopped whenever 8 or 10 inches of growth are made; this gives strength to the side shoots and lays a good foundation for the plant. Repot whenever the roots have reached the sides of the pots, being very particular that they never become pot-bound, which is sure to throw them into bloom (of course if bloom is required in a small state it is not necessary to repot as advised). Attention must at all times through the growing period be paid to shading, watering, and keeping up a moist temperature of 50° to 65°, which suits them admirably, and in which they make most rapid growth. They will require syringing at least twice a day, and the floors and stages must be frequently damped if the weather is at all hot. I often, when they are growing well and have made plenty of roots, water them overhead with a coarse-rosed watercan—a drenching which they seem to delight in.

The soil that suits them best is equal parts of good fibry loam and leaf soil or old hotbed manure (in which a great proportion of leaves has been used in the making), and a plentiful sprinkling of coarse silver sand, the whole well mixed together; plenty of drainage must be provided, and a layer of moss over the crocks will prevent the drainage from becoming choked. Liquid manure is beneficial when the plants are growing freely; it should be given two or three times a week provided it is not very strong; weak and often is the safest plan. With this treatment Fuchsias will be found to do well and make hand-

some plants for the conservatory, in which structure, if kept tolerably well shaded during bright sunshine, they will last in bloom until very late in the autumn.

When flowering is almost past water should be partially withheld and the wood be well ripened, and be allowed a period of rest in some places where frost is excluded. While at rest the plants should be pruned hard back, and about January be introduced into a temperature of about 50°. As soon as the buds have grown nearly an inch shake all the soil from the roots, and place them in smaller-sized and clean or new pots. If it is convenient the pots can be plunged in a very mild hot-bed, which assists them to root quicker and break earlier and stronger, and, if wanted for exhibition, stopping and training as advised must be attended to. Some of the early whites, such as Rose of Castile and Arabella, can be stopped as late as eight weeks before the show, but some of the doubles will require ten and twelve weeks, and the final potting should not be made closer than three months to the show. Should some of the plants as they become old not break well from the bottom cut them down, they will then with very little attention make useful bushes for conservatory decoration. I also train some plants as standards, which form associates well with other plants employed in grouping and massing.—J. W. MOORMAN.

WROUGHT-IRON STANDARDS FOR WIRE FENCING.

We have detailed on page 160 our high opinion of this kind of fencing. Messrs. Barnard, Bishop, & Barnards have sent us the accompanying wood-cut of their anchor-footed fencing, and state that the same heights may be pierced for any number of wires without extra charge.

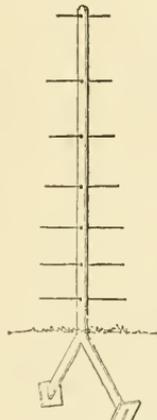

Fig. 28.

CARBOLIC ACID FOR SEEDS.

It answers admirably for both Wheat and Peas; but the mice or rooks will work the insides out of Broad Beans. A table-spoonful will dress a quart of Peas; sprinkle the dressing over them, after putting the Peas in a flower pot or basin, and stir with a label until all the Peas are covered. Three pints will dress two bushels of Wheat. It costs only 2s. 6d. per gallon. How it is mixed I know not; that I fancy will be a trade secret. Full instructions for dressing the seed are sent with the liquid, "King's patent carbolic dressing, prepared by Mr. Edmund King, Ashley, Cambridge."—J. DOUGLAS.

PROTECTING FRUIT-TREE BLOSSOMS.

NEARLY every year great damage is done to fruit trees by the severe frosts of spring. Last year spring frosts were most disastrous, and this year the blossoms are in a dangerous state. Much may be done by protection for preserving the crops on choice fruit trees on walls, and also pyramids; but orchards of course must take their chance.

I have noticed that destruction is frequently done during two or three nights. For weeks when protection is not needed it is afforded, and then when the "pinch comes" the covering is not sufficient. I allude now to permanent coverings such as nets, which occasionally first make the blossoms tender and then do not save them. When slender nets are used which exclude 4° or 5° of frost, there are almost certain to come nights of, say, 10° to 12° of frost, and then additional protection is needed to save the crops.

My opinion about the protection of fruit trees is this—The trees should not be covered at all unless absolutely needed, and then the screens should be sufficiently stout to resist 10° of frost. I have observed that the losses have been as great with trees which have been what I call half-covered during all weathers—mild as well as severe—as when other trees have not been covered at all. I will go further and say that I have known Apricot trees which have never been protected produce

better crops than others which have been screened with nets for weeks. I have no doubt but that others have noticed the same circumstance, for it is by no means uncommon.

Protection during mild weather renders the blossoms tender, and then when a rather severe frost occurs they succumb; while blossoms which have not been covered are more hardy and better resist the effects of a "nipping night."

It is self-evident that when, as is the case in some gardens, ample coverings are provided and they are judiciously used the crops are rendered safe. I mean moveable coverings of canvas or some other stout material. These are the best coverings, and the trees are well worthy of them. They are not, however, always provided, and the labour of pruning, pinching, training, and syringing, as well as wall space and root space, have been lost when frost has prevented the production of the crops.

The garden that I "look after" is only small in comparison with many others, yet it contains several wall trees and some profitable pyramids. The blossoms of these, or most of them, I have generally contrived to preserve. I have a length of herring net sufficient to cover the entire wall. That net I might place over the trees early in March and there let it remain, fondly hoping the blossoms would be safe; but knowing that such a net so used is only deceptive, I do not put it up in that fashion.

The only permanent coverings, if I may call them so, are a few bare poles. These are fixed during March, and remain until the end of May. Perhaps during that time the poles and trees are covered on twelve nights, rarely more, but frequently less, and during those nights they are covered well, at least as well as my means will permit.

As to the coverings, in the first place I must say that I have a conservatory to "look after." For this a canvas blind is provided for shading the flowers during the summer. This blind just covers the "best Peach tree" in the spring, and has always been effectual. The value of the fruit saved by this covering has been more than would pay for the canvas five times over; but still my "governor" would not buy other canvas for other trees.

After the conservatory blind comes the herring net; single it would cover the entire wall, but then it would not afford sufficient protection, so it is folded into five or six thicknesses, and covers a portion of the trees, and in that form it does its work well.

After the net come the mats (I have only a few of these), and after the mats the (and here is the advantage of being a groom) harness screen, horse rug, and other sundries. Out they come if the night is sharp and the time critical. What harm can a "night out" do such things as those? None whatever; it sweetens them and kills the moths, besides saving the fruit. But these do not cover all the trees, and then comes—straw; not straw, however, as a real gardener would use it (and here comes the advantage again of being a groom), but straw as used by the sometimes despised, sometimes valued, "horsey" man.

Have not gardeners often seen the neat fringes of straw fabricated by grooms and spread along the fronts of the stalls to make them look "trim"—a row of knots neatly made, and then a fringe of straight close straws? Well, these are first-rate "protectors." When made of "selected straws" each fringe will cover a surface of wall or tree of more than 3 feet depth. They are light, take up little room when folded, and with care they last three or four years. Three poles fixed round a pyramid Pear tree and covered with the straw fringe render the blossom of that tree safe, and the same on wall trees. Do not despise a groom; the gardener at the hall did not when he asked me to teach his men to make protectors of the same kind. The men—garden men—now make them on wet days, and they are used during frosty nights, and much fruit is saved that would be otherwise lost. If you print this I will tell you next week how I make miniature frames for raising flower seeds, &c., without infringing on anybody's patent. Mr. McSanderson, the baronet's gardener, says it is a capital idea, but not new. Old practices are sometimes as useful as new notions.—GROOM AND GARDENER.

BEAUTY OF GLAZENWOOD ROSE.

IN consequence of the Floral Committee of the Royal Horticultural Society having pronounced "Beauty of Glazenwood" to be identical with the old "Fortune's Yellow Rose," Mr. Woodthorpe, the nurseryman at Glazenwood, writes as follows:—

"I can only say I have bloomed the *Rosa* most decidedly and distinctly striped; but I have not bloomed it so well on the Manetti as on standard Briar. I will, if possible, send you some blooms during the summer."

[We can only repeat that the specimens exhibited to the Royal Horticultural Society's Floral Committee were not striped, but plain coppery yellow, and not differing from Fortune's.—Eds.]

ROYAL HORTICULTURAL SOCIETY.

MARCH 21st.

NOTWITHSTANDING that the Botanic Society's Spring Show was held on the same day, there was an excellent show in the conservatory at South Kensington. The exhibits were exceedingly choice, and well maintained the reputation of the different firms who kindly brought their collections. The principal exhibitors were Messrs. Veitch & Sons of Chelsea, Mr. Wills of Onslow Crescent, Messrs. Cutbush & Son of Highgate, Mr. Charles Turner of Slough, Mr. Aldons, Gloucester Road; Mr. Ollerhead, gardener to Sir Henry Peck, Wimbledon; Mr. E. S. Williams, Holloway; Messrs. Osborne & Sons of Fulham; and Mr. Gilbert of Burghley.

FRUIT COMMITTEE.—Henry Webb, Esq., V.P., in the chair. Mr. J. Maher, gardener to C. Allbans, Esq., Stoke Court, Slough, sent fruit of Eclipse Cucumber, for which a letter of thanks was awarded. Fruit of a Cucumber was received from Rev. J. T. Boswell from plants which have been raised from cuttings for many years, past in consequence of the fruit not producing seed. A letter of thanks was awarded. Mr. R. Gilbert of Burghley Gardens, Stamford, exhibited a collection of vegetables, consisting of very fine dishes of Seakale, Canadian Wonder Kidney Beans, Mashrooms, Hawke's Champagne Rhubarb, and Gilbert's Winter Cabbage. A cultural commendation was awarded. The last-named vegetable will be a valuable addition to the kitchen garden. Mr. J. Batters, Chilworth Manor Gardens, Romsey, sent a dish of Extra Early Vermont or Early Rose Potatoes, which were raised in 7-inch pots on the back shelf of a vinery and Fig house. The tubers were planted January 1st. A cultural commendation was awarded.

FLORAL COMMITTEE.—W. B. Callock, Esq., in the chair. Messrs. Veitch sent a grand lot of Hyacinths, Tulips, pot Roses, and Clematises. Among the former were some fine spikes of Baron Von Thyll, General Havlock, Blondin, Cavaignac, Von Schiller, Prince Albert Victor, Gigantes, Grand Blue, Garrick, King of the Blues, Lord Wellington, Masterpiece, Adeline Patti, Fabiola, Ornament of the Nature, Prince of Orange, Princess Louie, Lothair, and other double and single varieties. The Tulips from the same firm were equally well grown, and included most of the leading sorts. The *Roses*, which were much admired, included fine blooms of Princess Mary of Cambridge, Marquise de Castellane, Centifolia rosea, Mademoiselle Marie Baumann, John Stuart Mill, John Hopper, Victor Verdier, Marguerite de St. André, Madame Eugénie Verdier, Beauty of Waltham, Jules Margottin, Madame de St. Joseph, Brucine de Rothschild, and Madame Lacharme. Among Clematises, which are splendid decorative plants at this season of the year, were Lady Caroline Neville, Albert Victor, Lord Lonsborough, Miss Bateman, Lady Lonsborough, and other choice kinds. The collection occupied much space, and produced a splendid effect. A silver-gilt medal was awarded to Messrs. Veitch.

Mr. Allons's collection consisted of a very choice lot of decorative plants, including Palms, Azaleas, Spiræas, Tulips, Lily of the Valley, Cytisuses, Primulas, &c.; he likewise sent two large bouquets of choice flowers and one of *Roses*. A vote of thanks was awarded.

Mr. Ollerhead's group was made up of Azaleas, Rhododendrons, Dielytras, and some choice Orchids—*Chalcomopsis*, *Lycastis*, and *Cattleyas*, and *Odonoglossum*, including a very large variety of *Odonoglossum Roezlii* alba var. Peckii; they were in excellent condition and very effective.

Mr. Charles Turner's group contained excellent plants of Camellias, Azaleas, Hyacinths, Spiræas, and other plants, all of which were in superior condition, and were much admired.

Mr. Williams sent a fine specimen of *Imantophyllum* miniature with nearly twenty large trusses of flowers. This plant was placed at the entrance of the Show, and was particularly effective. A cultural certificate was awarded.

Mr. Wills exhibited a group of thirty varieties of his new hybrid *Dracænas*. Particularly noticeable were Gladstonii, Willisi, Leopoldii, terminalis alba, Elizabethæ, Bancsei, Victoria, Voluit, and Venusta. Mr. Wills also staged an elegant mixed collection in which the pretty halimoid of spring, *Myosotis dissitiflora*, was tastefully arranged with Lily of the Valley, and intermixed with *Isolepis*, small Ferns, and *Ficus repens*. A silver medal was awarded. Messrs. Cutbush & Son contributed a group of Hyacinths and *Eupracrias*, set-up in round baskets of about a dozen plants of each sort in each basket, and which had

a pleasing effect; and Messrs. Osborn & Sons, Fulham, staged an attractive collection of Palms, Hyacinths, &c., and Messrs. F. and A. Smith of Dulwich sent a stand of out flowers of *Cinerarias*.

A botanical certificate was awarded to Sir George Macleay, Bart., Blethieghley, for a *Tillandsia* from Jamaica. Henry Little, Esq., of Hillingdon Place, received a first-class certificate for *Cyclamen persicum Ruby*—a decided improvement, and a most conspicuous and ornamental flower. First-class certificates were awarded to Messrs. Veitch & Sons for *Poinsettia pulcherrima plenissima*, also for Croton McArthurian and C. Earl of Derby. A first-class certificate was given to Mr. R. Gilbert, Burghley, for *Primula Marobionæ* of Exeter, a fine double variety; and a similar award was made to Mr. R. Dean for *Primula purpurea*, also to Mr. H. Bennett for *Rose Duchesse de Vallombrosa*.

Mr. Dushell of Leighton Buzzard exhibited samples of different sorts of sand for horticultural purposes. The Exhibition was one of the most attractive and successful of the year.

ROYAL BOTANIC SOCIETY.

MARCH 21st.

ALTHOUGH the first "Park" exhibition was held on the first day of spring the weather was most unspringlike, for snow fell freely in the morning, and the north-east wind was unpropitious for plants and visitors alike. The date of the Show was in another respect unfortunate, as clashing with the meeting of the Royal Horticultural Society. Expressions of disappointment from exhibitors and others have not been few in consequence of the two shows occurring on the same day, and we know that both exhibitions have to some extent suffered, yet the Royal Botanic Society's first show was both extensive and excellent. There was a falling-off in the stove and greenhouse plants; but the Hyacinths especially, and bulbous plants generally, afforded full compensation by their numbers and quality. The Azaleas were also very good, and the exhibition in the mode of its arrangement reflected credit on Mr. Coomber.

In the class for twelve stove and greenhouse plants (open) Mr. Wheeler, gardener to Sir F. Goldsmid, Bart., St. John's Lodge, Regent's Park, was the only exhibitor, staging two *Imantophyllums*, two *Eriostemons*, a very good *Tetratheca*, *Cypridium villosum*, *Phalænopsis Schilleriana*, *Cochlostema Jacobinum*, &c., medium-sized plants in good condition, for which the first prize was awarded. For six hardy shrubs in flower, which was also an open class, only one collection was staged—by Mr. Moorman, gardener to the Misses Christy, Coombe Bank, Kingston-on-Thames. The plants comprised a large Ghent Azalea and a still larger Lilac, with medium-sized and well-bloomed *Rhododendrons*, *Prunus sinensis*, and *Andromeda floribunda*, to which the Judges awarded a first prize.

In the amateurs' class for six greenhouse Azaleas Mr. Ratty, gardener to R. Thornton, Esq., The Hoe, Sydenham Hill, was placed first for well-bloomed pyramids 4 to 6 feet high: the best light variety was Madame Cannart d'Hamale, and the most effective scarlet *Magnum Bonum*, Stella being also very good. Mr. James, gardener to W. F. Watson, Esq., Redles, was second with medium-sized double plants in good condition; and Mr. Wheeler third. In the corresponding class for nurserymen Mr. Turner, Slough, had the stage to himself. A fine plant of Belle Gantoise, rosy lilac, was very lovely; and Ferdinand Kegeljan, Duc de Nassau, and Apollo, white with pink stripes, were highly attractive.

For six Chinese *Primulas* Mr. James was awarded the first prize for good plants of a fine strain, Mr. Wheeler being placed second; and for six hardy *Primulas* Mr. Dean, Ealing, was the only exhibitor, and was awarded the first prize. *P. purpurea* was extremely beautiful, as also was *P. dentata*. The remainder comprised *P. altaica*, *P. vulgaris* Rosy Morn, a double white and a yellow duplex variety.

In the class for six forced *Roses* (nurserymen) Mr. Turner had no competitors; he staged admirable plants for the early season of a rose, foliage and blooms being alike good. Marquise de Castellane was very fine—the globular-shaped plant being 4 feet in diameter, and contained over fifty capital blooms. Paul Verdier was also excellent. The remainder consisted of Alfred Colomb, Céline Forester, Le Mont Blanc, and Souvenir d'un Ami. For six *Deutzias* (open), Mr. Douglas, gardener to F. Whitbourn, Esq., Loxford Hall, exhibited his well-grown columnar-shaped plants 4 feet high and 18 inches in diameter; but the whole of the flowers were scarcely expanded, consequently first honours went to Mr. James, Redles, for smaller plants in capital condition both as regards flowers and foliage; Mr. Douglas being awarded the second prize.

In the open class for twelve *Cyclamen* Mr. James secured first honours with splendidly-grown plants, each averaging 150 flowers, the foliage also being excellent. Mr. Edmunds, Hayes Nursery, Middlesex, was second with a very good collection; and Mr. Smith, Ealing, third. In the amateurs' class for six plants, H. Little, Esq., Hillingdon Place, Uxbridge, was placed first for very large plants but with rather small flowers, and Mr. James second with smaller plants but better flowers.

For six pots of Lily of the Valley Mr. Douglas was first with capital pots, the flowers and foliage being alike good; and Mr. Weir second.

Hyacinths were numerous and superior. In the open class for twelve plants there were six competitors, Mr. Douglas proving the victor with really grand spikes. The varieties were—Reds: Von Schiller, Vurbach, Koh-i-noor, and Fabiola. Blues: King of the Blues, Baron Van Tuijl, De Candolle, and General Havelock. Whites: La Grandesse and Mont Blanc, with Grandeur à Merveille, waxy white, and Ida, yellow. The second prize went to Messrs. Barr & Sguden for almost equally fine spikes. In this collection the best white was La Grandesse, the best red Vurbach, and the best blue Czar Peter. Third honours went to Messrs. Cutbush & Son, Highgate; extra prizes being awarded to Messrs. Osborn & Sons, Fulham, and Mr. Moorman, gardener to the Misses Chatter, the last being a very smart and excellent group.

In the amateurs' class for twelve plants Mr. Douglas was again pre-eminent, yet only a few points ahead of Mr. Moorman, who had the second prize, both the collections being admirable; the third prize going to Mr. Weir, gardener to Mrs. Hodgson, The Elms, Hampstead.

In the nurserymen's class for twelve plants Messrs. Barr and Sguden were placed first for splendid spikes, Messrs. Cutbush and Sons second for spikes only a shade behind them, and Messrs. Osborne & Sons third, also for an excellent collection.

Tulips were excellently exhibited. Mr. Douglas was first in the amateurs' class for twelve pots with the very best blooms in the Show of Vander Neer, White, and Pottebakker. Vermillion Brilliant, and Keyzers Kroon. Mr. Moorman was, however, close to the champion's heels with the same varieties, and had the second prize; Mr. Weir being placed third, also with good blooms. In the nurserymen's class for twelve pots Messrs. Barr & Sguden were placed first for capital pots of Joost Van Vondel, Cerise Gristleline, Vermillion Brilliant, and Proserpine. Messrs. Carter and Co. were second with vigorous and sturdy plants of Rose Luisant, Chrysolars, White Pottebakker, and Vermillion Brilliant; Messrs. Cutbush & Sons having the third place.

In the open class for twelve pots of Narcissuses in four kinds Messrs. Barr & Sguden won with large potsful (for the plants had not been grown in the pots in which they were exhibited) of Newton, Gloriosa, Bazelman Major, and Perle Blanche. Mr. Douglas was second with the same varieties and Perle Blanche. This was the more creditable collection, inasmuch as the plants were about as good as the others and had not been "made up," but were grown in the pots as exhibited.

Prizes were provided also for twelve bulbous plants in six varieties, distinct from any of the foregoing. Mr. Roberts, gardener to W. J. Terry, Esq., Peterborough House, Fulham, was the only exhibitor, and was awarded the first prize. The group comprised Muscari botryoides in four varieties, Lachenalia, Scillas, and Amaryllises.

In the miscellaneous classes some superior collections were exhibited. Messrs. Veitch staged a hundred Hyacinths, remarkable for the breadth and vigour of the spikes and the massiveness of the bells. The finest white was probably La Grandesse, closely followed, however, by Snowball, Mont Blanc, and L'Innocence. Amongst the light blues Lord Derby, Princess Mary of Cambridge, Czar Peter, and Blondin, were conspicuous; the finest dark blues being King of the Blues, Baron Van Tuijl, and Bleu Admirable. Amongst the nearly blacks Masterpiece was very noticeable by its depth of colour and fine bells; General Havelock by its massive spikes; Prince Albert also being superior. The best reds were Garibaldi, Prince Albert Victor, Pelissier, and Etna, the last-named being remarkable for its broad segments. The best yellows were L'Or d'Australie, Obelisque, and Ida. Messrs. Veitch also exhibited a large collection of Tulips.

A collection of 150 Hyacinths from Messrs. Barr & Sguden were staged in splendid condition, almost every spike being perfect. The collection embraced all the best varieties in cultivation. Messrs. James Carter & Co. also staged upwards of one hundred plants, but some of the bells were not fully expanded; they were, however, very good, as were the Tulips and Dielytras staged by this firm. Messrs. Cutbush & Son also staged a large and good collection; and Messrs. Osborn & Sons, Fulham, also contributed to the Show.

Messrs. Veitch further staged Clematises and a small but choice collection of ornamental-foliage plants, conspicuous amongst which we noticed a new Croton—Earl of Derby. This is decidedly the best of the trilobed section; the stem, petioles, and two-thirds of the leaves being canary-yellow, the remaining portion bright green. It is very striking. *C. varisabilis*, *C. McArthurii*, and *C. nobilis* were also exhibited; also new Ferns and Carnations and Euryclis australis.

Mr. B. S. Williams exhibited a large and attractive group of miscellaneous plants, including Palms, Dracenas, Orchids, Cyclamens, Yuccas, &c., in capital condition. The Rhopalas—Cercovandse and Juhngel—in this group had the commanding appearance. Mr. Turner, Slough, exhibited Carnation Rose

Perfection very fine, and cut blooms of superior quality of Gloire de Lyon, Mazaepa, and Fairy Queen. Mr. Edmunds and Mr. Smith staged large and good collections of Cyclamens, and Messrs. Wm. Paul & Sons, Waltham Cross, several boxes of cut blooms of Camellias in fifty varieties of the best sorts in cultivation. Conspicuous amongst them were the single varieties Coralina (velvety scarlet) and Elgans, rose. This collection was greatly admired. Single flowers of Cinerarias of good quality came from Messrs. F. & A. Smith, Dulwich. Certificates were awarded to Mr. James, Redlee, Isleworth, for the following Cinerarias:—Mrs. F. Watson, rosy crimson, white ring, flower of great substance; Mary, rosy pink, perfect in form; Thos. Winter, violet purple, very massive; Thos. Slenit, rich rosy maroon, very superior; Purple Gem, purple, white ring, immense size; Jane, rosy lilac, large and fine; Mrs. W. W. W., velvety purple, extremely fine. These are without doubt the finest Cinerarias which have ever been exhibited. Also to Messrs. Veitch for the following new Hyacinths:—Queen of Lilacs, rosy lilac, very distinct and fine; Marquis of Lorne, a bright lively blue, attractive; Reine de Naples, warm rosy salmon, with broad segments; Globosa, double white, gigantic bells; and Orange Queen, reddish crimson. Also for new Ferns—*Adiantum semulum*, somewhat resembling *A. assuile*, but more elegant; *Nephrolepis Duffii*, a very distinct dwarf species; *Asplenium pyrenaica*, a handsome and stately Tree Fern, and for *A. philippinense*; also for *Panax laciniatus*, *Euryclis australis*, and *Masdevallia chimera*. To Mr. Turner for Carnation, Rose Perfection, and to Mr. B. S. Williams for *Demosthenia dealoides* Youngii and *Panax laciniatus*. A similar award was made to Messrs. Rollison & Sons for *Panacea* roses, a distinct species with bright rosy flowers. It was found on the Grampian C. in Victoria at an elevation of 5000 feet. It will prove a valuable plant for the decoration of the greenhouse and for exhibition purposes. Certificates were also awarded to Mr. C. Edmunds, Hayes Nursery, Middlesex, for *Cyclamens roseum superbum* and White Swan. These were extremely fine and merited the distinction accorded to them.

NOTES AND GLEANINGS.

We are informed that the following gentlemen have consented to act as local honorary secretaries of the NATIONAL ROSE SOCIETY, and to promote its interests in their several localities:—Cauterbury: W. Mount, Esq.; Bath: R. B. Cater, Esq.; Cheshire: J. Tinsly, Esq.; Bromsgrove: R. Cordell, Esq.; Croydon: E. Mawley, Esq.; Exeter: R. G. A. Baker, Esq.; Hereford: the Rev. C. H. Bulmer; Maidstone: Hubert Bosted, Esq.; Leek: W. Newall, Esq.; Newark: the Rev. Canon Hole; Reigate: the Rev. Alan Chesley; Windsor and vicinity: G. Hawley, Esq.; Warrington: J. Hinton, Esq.; and Oxford: C. R. Ridley, Esq.

MR. BAKER, late gardener to Mr. Bassett, Sisters House, Clapham Common, and member of the Floral Committee of the Royal Horticultural Society, is well known as one of our best gardeners. Since his establishment in his new charge as gardener and bailiff to E. C. Baring, Esq., Coombe Cottage, Kingston-on-Thames, he has effected many improvements both in the re-erection of glass structures and in the ornamentation of the grounds. The plants and fruit houses in this garden are very numerous, but have been erected in the most strange manner imaginable, house having been added to house at almost all angles, and with all aspects except (strange to say), the south. A something like systematic arrangement is now being gradually adopted, and when an affluent gentleman of horticultural tastes and a gardener of admitted ability co-operate, good results are certain to follow. The houses are being well stocked, and plant culture, fruit growing, and vegetable forcing are in full operation. The details we cannot allude to now, but the gardens at Coombe Cottage are worthy of a note for the good order and condition of every department.

VARIOUS means are occasionally resorted to for preventing injury to the roots of CUCUMBERS and MELONS by the violent heating of the fermenting manure; but the simplest and best we have seen is the plan adopted by Mr. Denning in Lord Lonsborough's garden at Norbiton. The plants are planted as usual on hillocks, but before placing the soil on the manure a large flower pot—a 7 or 8-inch pot—is laid on its side and over this the cone of soil is placed, leaving, however, the bottom of the pot exposed through one side of the hillock, when, as may be readily understood, any excess of heat from the manure immediately under the roots of the plant escapes through the aperture of the pot, and burning is effectually prevented. As this is the period when Cucumbers are being largely planted Mr. Denning's safety-valve against root-burning is well worthy of attention.

— A FLORAL treat has lately been afforded by Messrs. Veitch & Sons to the inhabitants residing in the neighbourhood of the COOMBE WOOD NURSERIES. It is there where the renowned Hyacinths are grown preparatory to being exhibited, and previous to the departure of the plants for Chelsea they were open to inspection. We happened to see the plants when they were being prepared for removal. Each spike was carefully supported with a stake of stout wire bent near the bottom so that it could be inserted in the soil below the bulb. The bells were carefully arranged, a few being removed where too crowded, and the pots were placed in others an inch or two larger and the surfaces neatly mossed. The improvement resulting from the "dressing" as performed by Mr. Hill, the skilful grower of the plants, was very decided. The quality of the spikes has never been surpassed. Out of 1200 plants it would be difficult to find a dozen not suitable for exhibition. The first plant in the house, Lord Derby, we measured and found the spike to be nearly 14 inches in circumference. We will not now particularise the varieties, which are of the best. The forced Roses and Clematises are also in admirable condition. Indeed the nursery generally, which is highly picturesque, is in a superior state throughout.

— We recently saw growing vigorously in the soil of a Geranium pot at Messrs. Kollieon's Nurseries the curious parasitic plant OROBANCHE MAJOR. The two Asparagus-like heads of the parasite were just expanding their flowers, and the Geranium appeared to be in the best of health, notwithstanding the supposed pernicious effects of this parasite on plants growing near it.

— GABREA ELLIPTICA is generally considered of doubtful hardiness, hence it is deemed desirable to afford it a warm situation or a wall with a south aspect. We were pleased to see two plants forming the background of a drinking fountain in the village of Easington, in the North Riding of Yorkshire, with very healthy deep green foliage, and bearing their graceful long pale green catkins profusely. The plants are about a yard high, but their health and drooping catkins struck us as noteworthy, and not less the peculiar fitness of the plants for the position occupied, anything drooping associating well with water, whilst the dark foliage stood out in bold relief to the masonry. The plants have no shelter except a low Thorn or Quick hedge to the north.

— THERE is a very simple way of avoiding the disagreeable SMOKE AND GAS which always pours into the room when a fire is lit in a stove, heater, or fireplace on a damp day. Put in the wood and coal as usual, but before lighting them ignite a handful of paper or shavings placed on the top of the coal. This produces a current of hot air in the chimney, which draws up the smoke and gas at once. Not one person out of fifty, says the *Scientific American*, ever thinks of this easy expedient.

— THE correspondent at Alexandria of the *Daily News* writes: You will be glad to receive an account of the remarkable discovery of a NEW COTTON PLANT, which, from all reasonable appearances, is destined in a very few years to create quite a revolution in the cotton agriculture and business of Egypt. Signor Giacomo Russi, the Austrian consular agent in the most important cotton district, has published an interesting account of the discovery of the new plant. It was discovered on the cultivated property of a Copt in the Memna district about two years ago. It was found among other cotton plants, and at once attracted attention by its different appearance and also by bearing more pods. Next year he ascertained beyond all doubt that the produce was of a superior quality, and that its cultivation in Egypt presented no difficulty. So much interest was excited by the discovery that the small quantity of seed that could be collected was sold at twelve Egyptian sovereigns the ardeb—a high price when it is remembered that the very best seed of other cotton never exceeds £1 per ardeb. Signor Russi mentions that by many people the plant is supposed to be the growth of seed imported from the Brazils, while others think it the result of a mere chance combination of mixed seed. Signor Russi does not accept either view, and proceeds to describe the plant as having a long stem and being without branches, so that a good deal of space is saved in cultivation, to the advantage of course of the cultivator. The new plant bears on an average from forty-five to fifty pods, whereas the usual cotton plant averages from twenty-five to thirty-five.

— WRITING to us ON FAVOURITE TREES a correspondent states the last house inhabited by John Milton was in Queen Anne's Gate, Westminster, overlooking the Green Park. In

demolishing the house the stone tablet erected to his memory and affixed to the wall by Jeremy Bentham, who afterwards occupied the next premises, has been carefully preserved. It is about 2 feet square, and bears the following inscription:—"Sacred to Milton, Prince of Poets." It is said that when Bentham took visitors to view the house he compelled them to kneel before the slab. The Mulberry tree planted by Milton, which was so severely scorched at the fire at Mr. Hankey's, is fairly recovered, and that gentleman, who is carrying out the work of demolition and the erection of colossal mansions on the sites, is extremely anxious as to its welfare. The Ash tree in Beaufield churchyard, beneath which Edmund Waller rests, is well preserved. Shakespeare's Mulberry tree and Rousseau's Walnut tree are all renowned.

— Now that forced flowers play such an important part in the decoration of conservatories during the spring months, the value for that purpose of the JAPANESE AZALEAS (*A. mollis*) must not be overlooked. A mollie was raised from seeds imported from Japan by C. Maximowicz. To the late Mr. Van Houtte must be ascribed the honour of distributing this tribe of Azaleas in several fine varieties, and which are gradually finding their way into many gardens. The flowers are much larger than those of the Ghent Azaleas, and are varied in colour, the plants producing dense masses of flower. A few fine varieties which we have recently seen are Comte de Gomer, rose, orange apots; C. Francois Luppis, rose shaded with magenta; Comte de Quincy, yellow; M. Charles Van Wambeke, orange and rose; Alphonse Lavallée, orange and scarlet; and Dr. Leon Vignes, white spotted with orange. They are quite hardy.

— FEW flowers are more valued during the winter months than WHITE CAMELLIAS, and one of the finest that has recently come under our notice is La Vestale as exhibited at South Kensington by Mr. Charles Turner. Although this was placed in a stand with other white blooms its purity, smoothness, and superior texture of petal were conspicuous and greatly admired. If the plant is as free in growth as the flower is good in quality it must take a foremost place in choice collections of these winter flowers.

— THE total amount that has been contributed in response to the appeal made by Mr. Luckhurst on behalf of the widow and eight young children of the late T. C. SAGE, who by his sudden death were left totally unprovided for, is £32 14s. 6d. This sum has been handed to Mrs. Sage, who is most grateful, and earnestly desires to express her heartfelt thanks for the kindness and sympathy shown to her in her great distress and sorrow. Subscribers to the fund will be glad to learn that the money has been applied to the opening of a small shop for the sale of toys and fancy goods at 9, Crown Road, Fulham, and that, notwithstanding Mrs. Sage's delicate health, the venture is prosperous, and is likely to continue so.

— A GERMAN journal recommends for the preservation of CUT FLOWERS almost indefinitely, either singly or in bouquets, that they be dipped in a solution of pure albumen, and after allowing them to become perfectly dry that the operation be repeated several times, each time with fresh albumen. The white of an egg is nearly pure albumen.

— ONE of the most effectual of deciduous shrubs for forcing for conservatory decoration is the GUELDER ROSE (*Viburnum opulus*). Messrs. Veitch force many plants of it, and they are in great demand for decorative purposes. Plants in 8-inch pots will produce heads 2 to 3 feet in diameter, and these when covered with twenty to thirty "snowballs" are extremely effective. A shrub so easily cultivated and prepared for forcing should be increased and grown in all gardens where spring flowers are in request and means are provided for producing them. They may be grown as standards of from 2 to 6 feet in height, according to the purposes for which they are required, and few plants will be more conspicuous at the period of their flowering—February and March onwards.

— We have received a copy of the sixth edition of "AGROGEOGRAPHIA," a treatise on cultivated Grasses revised for the Lawson Seed and Nursery Company by Mr. David Syme. Mr. Syme has done his work well, having given historical notes of the Grasses, with the uses and adaptations of the most important species, which are also represented by coloured figures. The treatise is both useful and entertaining.

— ALTHOUGH it has suited the purpose of some writers to be factitious when referring to the COLORADO POTATE BEETLE, regarding it almost as a myth and its transit across the

Atlantic an impossibility, yet according to the evidence of the Earl of Carnarvon in the House of Lords the insect is now established in Europe, and orders in Council have been issued preventing its transit from Germany to England. It is calculated that in the course of the summer the insect brings forth three generations, and that a couple of Colorado beetles will annually produce fourteen thousand insects. The following is the history of the pest. It was first perceived in America in 1823 in the Rocky Mountains. As it did not find sufficient food in the barren soil of those parts it emigrated to more fertile land, and finding the Potato to its taste fastened upon it in preference to all other food. Thus in a short time all the Potato fields were devastated. In 1859 it caused immense mischief in the territory of Nebraska; in 1861 it overran the State of Missouri and was observed in Iowa. In 1865 it entered Minnesota, and in the following year it crossed the Mississippi River and invaded the States of Wisconsin, Illinois, and Kentucky. In 1870 it appeared in the States of Michigan and Ohio; the lake of the former proved no obstacle to its advance. In 1871 it penetrated into Canada, Pennsylvania, and New York. Lastly, in 1874 ships brought it over to Germany in boxes containing Potatoes. The insect was concealed in the earth that enveloped the tubers and in the dry leaves in which they were packed.

— We have received from Mr. Abbey some BUNCHES OF VIOLETS taken from plants which have been flowering in frames since October. Though the plants have bloomed for nearly six months the flowers now produced are very superior. Especially fine is the true Neapolitan, of which there are several varieties, the one sent having been received from Florence. It is the finest, sweetest, and most floriferous of all double Violets. Victoria Regina is the best of the singles excepting Prince Consort, which is lighter—nearly blue—in colour. We never saw finer Violets than these, nor cleaner and better foliage.

— The following are the “vivid imaginings” of an American mind who has been haunted with the FRANKS OF THE PANSIES. “There is something about Pansies charmingly companionable, social, fairy-like. They look at you in a knowing way, and nod their heads, and once in a while you will see one hid away in the leaves, actually ‘laughing in his sleeve’; and if you look pretty sharp you will be very apt to detect some impudent fellow ‘making faces’ at you. We have observed that they do this more frequently and boldly just about dusk.”

— “I HAVE lately,” writes Mr. Darwin in “Nature,” “received an interesting letter from Fritz Müller in St. Catharina, Brazil, on the subject of HYGROSCOPIC SEEDS. He tells me that in the highlands of the Uruguay he has succeeded in discovering more than a dozen Grasses, as well as a species of Geranium, whose awns are capable of hygroscopic torsion. The most curious among the specimens received are the seeds belonging to the genus *Aristida*. In one of these the awn is longitudinally divided into three fine tails, 6 or 8 inches in length, each of which twists on its own axis when the seed is dried. These tails project in three directions, and more or less at right angles to the axis of the seed, and Fritz Müller states that they serve to hold it in an upright position with its lower end resting on the ground. The seed is pointed and barbed in the usual manner, and when it is made to rotate by the twisting of the awns, it evidently forms a most effectual boring instrument, for Fritz Müller found many seeds which had penetrated the hard soil in which the parent plant was growing. In another species of *Aristida*, as the tails wind together and form the strands, the seed is made to rotate and thus bury itself in the ground.”

HYACINTHS AFTER FLOWERING.

A SHORT time ago a suggestive letter on the importance of preserving and maturing the foliage of Lilies of the Valley appeared in the Journal from the Hon. and Rev. J. T. Boscawen. The force of Mr. Boscawen's observations have no doubt been appreciated by many readers, for, as was remarked in connection with the letter, without good foliage there can be no perfect flowers. If that observation applies, as it does apply, to the one prime essential in the support and maturation of the rhizomes and crowns of Lilies, it applies with at least equal force to the sustenance and ripening of the bulbs of Hyacinths. Without good foliage there cannot be good bulbs, and without good bulbs there cannot be good flowers. That is

the logic of facts, and it is easy to be remembered by all who have latterly been indulging in the pleasure of growing Hyacinths, and who desire to preserve the bulbs in as good a condition as possible for producing flowers in future years.

Hyacinths are not annuals, to be flowered once and done with; they are perennials, and with ordinary care will yield perennial beauty. It is not suggested that the spikes produced by Hyacinths in future years will equal in size and beauty those which were produced during the first season's flowering in England. The bulbs on arrival from Holland were at their best—the zenith of their maturity; but that is no reason that they should be destroyed immediately afterwards, any more than a fruit tree or a horse should be “put out of sight” by violent means when the first signs of declining vigor have become apparent. Rather should the waning resources—valuable even if declining—be aided, in order that a maximum of value may be derived over as long a period of time as possible.

Than Hyacinths no flowers are more popular, none more easily managed, none more extensively cultivated. The number of purchasers of bulbs are increasing yearly, and would increase still more could the bulbs be induced to produce flowers year after year instead of making one “grand flash,” like the *finale* of a pyrotechnic display, and then “done with.” Hyacinths are imported by millions; but what becomes of them? Why, they are killed. There is no reason that this should be so, but every reason why they should be preserved. Until the flowering period they are treated with solicitous care, and air, light, and water are provided to render them as perfect as possible; but as soon as flowering is over the three essentials are no longer regarded as important, yet they are as important as ever in producing good foliage, which is the certain forerunner of good flowers during the following year.

As soon as the flowers of a Hyacinth have faded the spike should be cut, or seeds will possibly form, which are more exhaustive than the flowers. The foliage should then be induced to make vigorous and prolonged growth by the assistance of good food—manure water, and under the influence of sun and air. Early-flowering Hyacinths can only have their growth perfected by being kept in artificially heated houses; but others (and these are the great majority) which flower late—*i.e.*, in March and April, need nothing more than a cold frame, or even the shelter of mats, to preserve the foliage from injury after flowering has ceased. It should be remembered that the foliage of Hyacinths which have been grown under glass is as susceptible of injury by sudden exposure to the sun as by the influence of a low temperature. There must be no flagging, scorching, or discoloration that can be prevented by shade, shelter, and attention. The plants should be gradually hardened, and when green and healthy may be planted out closely together in light soil. There they may remain until the foliage decays, when the bulbs may be assorted and stored until September, when they may be potted or planted where they are required to flower. Some of the bulbs, if the management has been judicious, will produce very good spikes, while others will not be worthy of being potted, but may be planted where they can remain and increase. These preserved bulbs, which are again potted, should only be regarded as supplementary to the Dutch-grown bulbs which are potted singly for producing stately spikes, the home-grown bulbs being potted three to five in each pot for producing masses of smaller spikes, which are very beautiful, and are invaluable for yielding out flowers and conserving the principal spikes.

As an instance that the preservation of forced Hyacinth bulbs does not militate against the purchase of superior Dutch-grown produce I can adduce very good testimony. Some years ago on taking charge of a garden the owner stated that he was tired of buying Hyacinths, which he could only enjoy one month, the bulbs being then “exhausted and wasted.” I bought a dozen myself, and so managed them that they nearly all flowered well the second year. When my employer saw this he was encouraged to purchase, and he now does not hesitate to buy a hundred bulbs annually where he once refused to buy a dozen. His garden is now, to use a common phrase, “full of Hyacinths,” which each year produce a charming effect, and afford hundreds of spikes for cutting and distributing amongst friends. This is simply the result of preserving in the best manner possible the forced bulbs by encouraging the growth of good foliage after flowering by the assistance of generous treatment, light and air.

Hyacinths which have flowered in water should as soon as possible be carefully placed in leaf soil or cocoa-nut fibre refuse, and be kept moist so as to preserve the foliage as long

as possible. The bulbs can afterwards be planted in light rich soil, and in two years and onwards they will produce attractive spikes. These bulbs are of little use for potting; but Hyacinths which have flowered late in pots are, if well and carefully managed, very valuable in future years.—A DOCTOR'S GARDENER.

FICUS PARCELLII.

FRESH interest has been evinced in this beautiful variegated stove plant since it has arrived at a fruiting state with some cultivators, and from the fact that the fruits are attractive as well as the foliage. To many the plant is well known, but,

remained there until the third week in October, when they were removed to a cold house. In the month of December they began showing signs of growth, and they were shaken out and repotted into pots from 7 to 9 inches in diameter, the compost used consisting of two parts of loam and one of leaf soil, with enough pounded charcoal and sand to give porosity, rubbing a liberal quantity of dried cow dung into the whole. They were potted moderately firm. About the middle of January they were placed in ainery having a night temperature of 50°, rising to 60° in the daytime with sun heat. As soon as the pots were filled with roots they were supplied about twice a-week with manure water in an almost clear state,

Fig. 29.—FICUS PARCELLII.

judging from letters which we have received, there are others to whom it is not familiar. Messrs. Veitch & Sons have enabled us to publish a truthful representation of a leaf of the plant, which is conspicuous from its distinct colours and their decided contrast. The plant, we need only add, is of easy culture, and is very useful for general decorative purposes.

SPIRÆA JAPONICA CULTURE.

THESE is now flowering in the conservatory of C. Massey, Esq., The Beeches, Newcastle-under-Lyme, some fine specimens of the well-known *Spiræa* (*Hoteia*) *japonica*, a plant which deservedly holds a foremost place amongst our spring-flowering plants, especially where there is any demand for cut flowers. The plants alluded to are bearing from twenty to twenty-five spikes of bloom on each, one in particular having thirty, with its beautiful foliage measuring nearly 3 feet across.

Mr. S. Kirkham states the following as his mode of culture. The plants were forced last year in 6-inch pots, and were afterwards placed in their pot outside under a fence having a western aspect, and, being supplied with abundance of water,

made from the scrapings of the poultry yard, until the flowers began expanding, when it was discontinued. The plants are now in the conservatory, and are admired by all who see them.

HAMPTON COURT PALACE AND GARDENS.

THIS royal palace is delightfully situated on the north bank of the river Thames, fourteen miles from London. It is embellished by nature as well as art, and is historically associated with the lives of illustrious men. It was built by Cardinal Wolsey, who is said to have provided here two hundred and eighty silk beds for strangers only, and richly stored it with gold and silver plate. It caused so much envy that he gave it to King Henry VIII., who in return allowed him to live in his palace at Richmond. This king greatly enlarged Hampton Court. Queen Elizabeth adorned it with pictures and other ornaments, but King Charles I. is mentioned as having given his personal attention to the garden. The semicircular garden spreading from the terrace of the east front was planned by him. We are informed that Charles II. superintended the royal garden if any alterations were going on, or he was fond of out-

door exercise; and it was here that he observed to some who were reviling our climate and extolling that of Italy, Spain, and France, that he thought that was the best climate where we can be abroad in the air with pleasure the most days of the year and the most hours of the day, and this he thought could be in England more than in any other country.

King William III. and Queen Mary made great improvements, both in the palace and the grounds. The old apartments were pulled down and rebuilt as they now appear. The private garden on the south side of the palace was sunk 10 feet to open a view from the apartments to the river. It was surrounded with a tall hedge to shelter from the winds such exotic plants as were moved hither from the conservatories. There are two basins constantly supplied with water for the supply of the plants in dry weather. The plants were seen from the windows of the royal apartments, and in this part of the garden the Queen took great delight, and was so fond of tender

exotic plants that she allowed a handsome salary to Dr. Plukenet for assisting to arrange and regulate her plants, also to register all that were received. This part of the garden is tastefully laid out, and is the work of those two eminent gardeners, London and Wise.

On the north side of the Palace is the wilderness garden. In the olden times it was the custom for a portion of the pleasure grounds to be in as natural a state as possible, making a strong contrast with the exact symmetry which everywhere prevailed. In the Dutch geometrical garden, where every tree was planted with exactness, evergreens were indispensable. The Box, Holly, and the Yew, with two or three others, made up the furniture of the garden; the scissors and the shears were the principal garden tools; clipping and pinching were scrupulously carried out; cones and pyramids, and forms of beasts and birds, rude copies of works of art were made, and of these, topiary works as they were called, the remains may

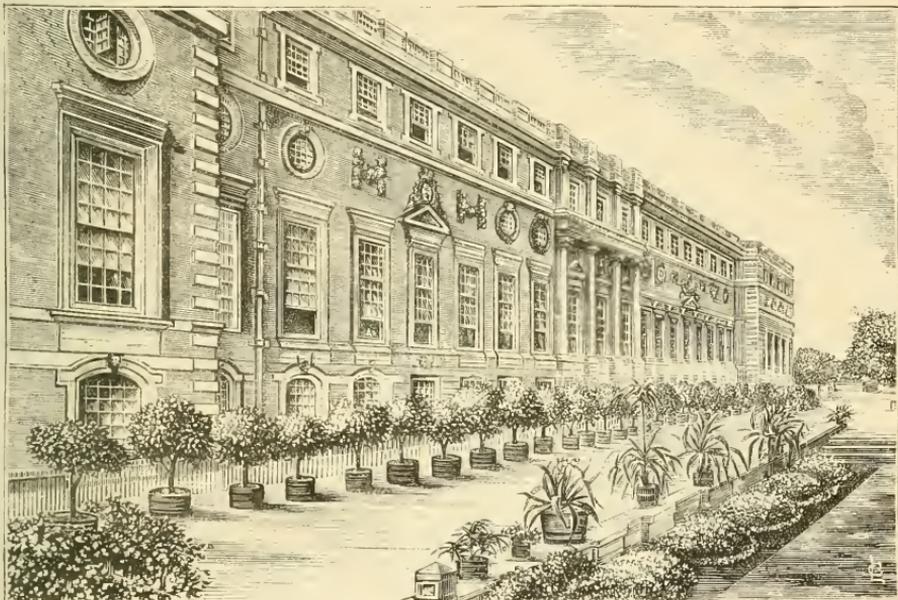

Fig. 33.—HAMPTON COURT PALACE—SOUTH TERRACE WALK.

now be seen, but most of the trees have grown into their natural shape.

Of this garden, which was considered one of the finest in England, Horace Walpole recorded his great admiration; those fanciful figures appeared to him interesting and beautiful from the variety of objects exhibited, and were pleasing to the eyes of Addison and others. They admired the neatness and the workmanship, and would not have a single specimen destroyed.

The taste for natural scene, has much improved of late years, and the specimens of ancient gardening are now esteemed as remains of antiquity. The most distinguished are those grand avenues of Hampton Court and Windsor Castle. They are noble examples worthy to be imitated, for there is something grand and venerable about long green avenues and broad carriage drives. No trouble or expense has been spared to adorn the garden with the choicest flowers, and for the lovers of trees there is no place more interesting. Trees that were beautiful two hundred years ago are picturesque now, and such trees are the most esteemed ornaments in our modern pleasure grounds. There are some very venerable specimens. The Limes have attained a large size, many of them being 12 feet in circumference and 100 feet high. The Elms are conspicuous for size and beauty, measuring 25 feet in girth. The Oaks are gigantic in size, one measuring over 40 feet in girth near the ground. It divides into three large limbs of nearly

equal size. The Horse Chestnut trees are favourites with the Londoners, and their splendid foliage and fine spikes of flowers entitle them to be considered one of our most ornamental trees, and are a beautiful addition to the appearance of this place. The artificial decorations, fountains, statues, and vases are in harmony and pleasing contrast with the natural ornaments.

The gardens are well managed, and last year the flower garden was admitted to be equal to those in the London parks. The "great Vine" is increasingly popular. It is in what is known as the "private garden," and it is annually visited by thousands of sight-seers, to whom the two to three thousand bunches of Grapes are something to be wondered at, and, perhaps, coveted during the sultry days of summer.—N. COLLE.

JACOBÆAN LILY.

SPREKELIA (AMARYLLIS) FORMOSISSIMA was introduced as far back as 1658, and I believe was formerly more generally cultivated than it is now. Although treated as a stove and greenhouse plant it is said to be perfectly hardy. I have not proved this, but I believe my authority is reliable. The requirements of the plants are few and simple. I will suppose the plants are in bloom in April. The flower scape appears before the leaves. As the leaves advance the plants should be attended to with water. When the foliage turns yellow water should

be gradually withheld until the bulbs are matured, when they may then be stored away in some cool dry place. The secret of success in flowering these Lillies is a long season of drought or rest. They should be potted in well-drained pots in a compost of good sound loam, well-decomposed vegetable matter, and coarse sand or charcoal dust. They are the better for being potted some time before they are expected to start into growth. When root-action has commenced they should be supplied with water as they may require it; and when fairly growing, if they can be taken into a gentle heat, the scape will soon appear. When in bloom their beauty will well repay any amount of labour that may have been bestowed upon them. Where there is a stock of bulbs, with careful observation and notes they may be had in bloom for a considerable time. They are increased by offsets. I should be glad to have further evidence respecting the hardness of this old favourite.—SCAPACEOUS.

GUMMING AND CANKER.

The cause of gumming, that is, the extravasation of the sap of certain fruit trees, has not, I think, been clearly traced to its source in every instance. Heat is said to be one of the principal causes of this evil, but what will the advocates of such a theory think when I assert that cold appears to me to exercise an important influence for evil in this matter? In making this statement I must own that I am not prepared to say that gumming does not sometimes arise from heat, but it should not be forgotten that in attributing it to heat we infer that it proceeds from some internal disorders, some derangement of the system—in point of fact, that the disease is organic, and consequently incurable, as, indeed, the swollen gouty appearance of the joints of some trees that are badly affected might fairly induce us to suppose.

Göthe, in showing that all trees and plants consisted of two parts only—leaf and stem, that the bark is simply an extension of a leaf, the roots and branches just so many prolongations of the stem—did good service to science, and taught a lesson of such importance that a clear comprehension of its full significance ought to enable one to trace every disease, and especially gumming, to its source more readily and with far greater certainty than could be done without such knowledge. Regarded as a portion or rather extension of the leaf, the texture of the bark assumes a much greater degree of delicacy to the mental vision, and these follow a consequent realisation of the harm which may happen to it from rough treatment, or even from undue exposure. Bruises and wounds from blows with the trainer's hammer or mallet, from clumsily driven nails, neglected fastenings of string, wire, and even of cloth shreds, are by far too common, and every one of them entails a risk of gumming which in reality often follows. The exposure to severe frost of the delicate outside of the unripened growth of the Peach and Nectarine induces canker and premature decay. Thus, young trees of both species having the protection of a wall sometimes present the anomalous appearance of growth of extraordinary vigour blotched with disease, as though the bark had been in contact with some burning substance, destroying its tissue and causing the wood to decay. Now these plague spots invariably make their appearance upon the exposed side of the branches and never upon the side touching the wall; it is therefore self-evident that the mischief proceeds from external causes and not from any disorder of the system. Moreover, it is reasonable to suppose that the green crude bark of a gross unripe shoot would be more susceptible of injury from frost than that of wood which not being so rampant has come to its full maturity earlier in the season.

Certain sorts of Cherries are subject to attacks of gumming, others to canker, and it is curious to observe how each form of disease is developed in different sorts. In *Empress Eugénie* gumming presents itself upon the close-pruned lateral growth, the stem and main branches presenting the aspect of perfect health in contrast to this. Early Purple Gem has swollen gouty joints, the stem and branches sometimes absolutely glistening with extravasated sap. This was notably the case in a dwarf-trained tree of this useful early variety which was planted by mistake against a north wall, the gumming being so bad as to give a severe check to the growth and endanger the life of the tree. It was this particular example which convinced me that gumming sometimes proceeds from the effects of cold. The effect of canker is far more serious, sometimes killing a tree outright, and always destroying the branch which

it attacks. This, to my surprise, has been my experience of it with the Kentish preserving Cherry, several trees having suffered severely from its ravages. I may add that the soil in which they are planted cannot be termed a bad one for the Cherry, as the greater number of some thirty varieties are in a flourishing and perfectly satisfactory condition, and the wild Cherry attains to the size and bulk of a timber tree in the adjoining woods.—EDWARD LUCKHURST.

FLOWER CLASSES.

My remarks are chiefly confined to the queen of flowers—the Rose, but I think they are equally applicable to most of the flowers usually found at shows.

We know how important for the production of good blooms is a good pure atmosphere together with good soil; and yet at shows in the amateurs' classes, those who live in the vicinity of London and our other great towns have to compete with others whose Roses grow in first-rate soil surrounded by fresh country air. Now cannot we have a class or classes for exhibitors who reside within five miles of the City?

Then as to the number of blooms to be exhibited. It is but seldom that we see a less number than twenty-four varieties, and generally they are required to be in sets of three trusses of each. For those who have plenty of room and other favourable circumstances this is very well; but there are others who, like myself, would wish to see their pets on the exhibition table, but who could never hope to have seventy-two blooms in perfect condition at one time. My own Rose garden consists of a border about 80 feet long by 9 feet wide. Why cannot we have a class of ten or twelve varieties of one or two blooms each?—A WOULD-BE EXHIBITOR.

PROTECTING PEAS WHEN SOWN.

Drop the seed into benzoline and sow at once. Nothing will touch the Peas under ground or when above ground. I have just sown some British Queen Peas soaked all night in a solution of aloes. I do not believe mice will touch them. Some were sown without dressing, and as soon as they appeared were earthed-up like Potatoes. Last year this succeeded.—W. F. RADCLIFFE.

WINTERING ALTERNANTHERAS.

Since carpet bedding has become the fashion in nearly all gardens now, plants suitable for that purpose must be cultivated, and the *Alternantheras* are a class of plants that have become very popular, and deservedly so, for their dwarf habit and the beautiful shades of colour that can be produced with them in carpet or tracery bedding render them at present indispensable; but the difficulty experienced with many is the keeping of the plants in good condition through the winter, and for the benefit of your readers who have asked for advice on that point I shall relate my treatment.

Towards the end of July the plants will have made good growth, which enables us to take cuttings. These are inserted in 6-inch pots filled three parts with drainage, the remaining part with a mixture of loam, leaf soil, and a sprinkling of charcoal dust and sand. In this the cuttings are inserted thickly, each pot holding from twenty to twenty-five cuttings; they are then placed in an old Melon or Cucumber bed, first levelling the bed and covering the surface with some coal ashes, on which the pots are placed and well watered. The frames are then kept rather close and shaded during bright days, and the cuttings sprinkled when the atmosphere of the frame seems too dry, or the leaves show any signs of flagging. With this treatment the cuttings soon form roots, and air is freely admitted on fine days. On the approach of cold nights the plants are removed to the Pits stove, or any glass structure where a heat of from 60° to 70° can be commanded. Here they remain for the winter, receiving enough water to keep the soil moist until February, when I have them taken out of the cutting pots and planted about 2½ inches apart in boxes. These are then taken to the Cucumber pits, where the plants soon become established. The moist heat of these structures suits them admirably. They are afterwards placed in late vineries, where they receive more air, and eventually are hardened off in cold frames previous to planting out. With this treatment I can guarantee ninety-nine cuttings (if not more) out of the hundred. I find them do remarkably well in the boxes, and where large quantities are required they are much less trouble

than pots and take up less room. The varieties we grow here are *Alternanthera magnifica*, *A. amabilis*, *A. paronychioides*, *A. latifolia*, and *A. amena*. The last-named I find requires a little special treatment. It is necessary to have good plants of it to plant out, also to plant them thickly, for when once the plants assume their deep colour in the leaves the growth is very slow; it is likewise best to have some stove plants to place in heat to propagate from. They will grow luxuriantly and the leaves will be almost green, but I find the cuttings give far more satisfaction from these than from the high-coloured outdoor plants.

All the *Alternanthera*s are strictly speaking stove plants, and the reason of the failure we often hear of in winter is through the plants being subjected to a temperature far too low. In a temperature ranging from 60° to 70° they seem at home and comfortable.—*J. ANDERSON, Hill Grove.*

BEEES IN FRUIT CULTURE.

THE last (third) report of the Vermont Board of Agriculture, Manufacture, and Mining, contains a paper by James F. Crane of Bridgeport, on the relation of bees to fruit culture, in which the importance of the presence of bees as agents of fertilisation in the period of bloom is shown by numerous examples. The first of these runs as follows:—"In 1774, Count Anthony, in Bavaria, President of the Academy of Science at Munich, proved by official family records that a century earlier, when bees were kept by every tenant on the estate, fruit was abundant, whereas then, when only seven kept bees, and none of these kept more than three colonies, fruit was scarcer than ever among his tenants." The count's conclusion as to cause may or may not have been right; but it raises the practical question whether there is not also a relative decline in bee-keeping in the United States as compared with the great increase in fruit-growing and attempts at fruit-growing. There has been, we think, a marked decline in the "setting" of fruit, which all have attributed to weakened trees, cold rains, &c.; but it is worth considering whether the lack of the "little busy bee" is not also a cause of barrenness.

Our only way of ascertaining the relative progress of fruit culture and bee culture is by reference to the census, and that gives us the following figures:—

	Val. Orchard Products.	Wax. lbs.	Honey. lbs.
1840 ..	\$ 126,756	29,173	..
1850 ..	446,049
1860 ..	1,126,128	56,730	1,846,803
1870 ..	8,571,789	46,262	1,547,178

This would indicate a much smaller increase of bees than of fruit trees and Vines. In thirty years the value of orchard fruit has increased thirtyfold, while the products of bees have hardly doubled. Each bee may be said to have fifteen times as many fruit blossoms to visit as the old-fashioned hummers of 1840; and the fertilisation may be done with corresponding imperfection, especially in a time of cold rains with little sunshine.

Again, it is to be considered that cold winters destroy bees as well as injure fruit trees, and that consequently, in the years following a winter of intense cold, there are a less number of bees to act as conveyers of pollen from flower to flower as well as, it may be, a greater need of fertilisation in enfeebled blossoms.—(*Prairie Farmer.*)

MYOSOTIS DISSITIFLORA.

MUCH praise has been justly bestowed on this very beautiful spring flower. A bed of it is indeed charming, and its utility for indoor decoration is highly valued by all who have grown it for this purpose. Your correspondent on page 34 has not in the least exaggerated its merits; but I now write to say that I have succeeded in raising from *Myosotis dissitiflora* a seedling far exceeding its parent in beauty. The flowers are larger, many of them being more than half an inch in diameter. The segments are broader, giving the flowers a very compact and rounded appearance, while the colour is quite equal to that of its parent. I found my first plant last spring in a bed of *M. dissitiflora*. I immediately raised the plant, and by the month of October it had grown 1½ foot across, having blossomed and seeded freely. I have now some portions of the plant in pots flowering freely in a cool orchard house. The seedlings of the above plant are also flowering, the flowers of these being somewhat larger than those of the parent plant, which I attribute to the greater vigour of the seedlings. The plants

are grown in loam and leaf soil without any manure whatever. I send herewith a specimen for your inspection. The original plants of *Myosotis dissitiflora* from which the seed of this variety was saved were grown in company with others of *M. grandiflora* in the vicinity of an apiary.—*W. GROVES, Shortlands, Kent.*

[The flowers are fully as large as represented by our correspondent; it is a promising variety of a popular flower.—*Eda.*]

PEACH FORCING.—No. 8.

THINNING.—No other fruit exhibits in so marked a degree the effect of overcropping as does the Peach. With a redundancy of blossom the setting of the fruit is much less certain than with a fair number of bold healthy blossoms, or if many blossoms set few well larger than peas before dropping, or they collapse when commencing stoning, and while, if too many remain for ripening, the fruit is small, having little flesh, not much juice, and next to no flavour.

The effect of overcropping is not, unfortunately, confined to the present crop, but its direful influence is felt in the next season's result. A tree carrying a heavy crop makes very little growth, and so much of it is appropriated to the maintenance of the present crop that the growths for affording the crop of the succeeding year are ill-nourished, and the buds do not attain full development, consequently many of the blossoms are small and imperfect, dropping without first casting the petals, which is not the case with perfect flowers.

Judicious and early thinning can hardly be too strongly insisted on. It is very pleasing to see a tree studded with young swelling fruit, but it does not always occur to the observer that if two fruits are left where only one ought to be, is diminishing the size and quality of the latter by half. Some have so great a dread of the fruit being cast at stoning time that they leave two fruits where they only intend to allow one to ripen, resulting not infrequently in both dropping, and just as frequently in both remaining. The changes are not on that account equal, for most fruits pass the stoning safely when the crop is thin, therefore with a fair crop we may safely conclude that we shall have no difficulty in effecting their stoning, and I should like to know if we allow but one fruit in place of two to grow until stoning if that fruit will not be much larger at stoning and have a better chance of being finer than had we allowed two to remain?

After the fruit is the size of horse beans thinning should commence. The trees being furnished with shoots upon the branches a foot apart we may safely reduce the number of fruits to two on each branchlet, and even so early we must see to the position of those retained with regard to their having room for attaining their ripened proportions without coming into contact with the trellis or branches adjoining, and if possible have the fruit so disposed that it be equally exposed to light on all sides. When the fruit is the size of a small walnut we may take off the smallest, ill-shaped, and badly disposed of the two fruits left upon each shoot for stoning and ripening. What if a few are lost in stoning; those remaining will be all the finer, and the certainty of future crops be better insured.

No Peach of the large kinds, as *Noblesse*, *Grosse Mignonne*, &c., ought to have less than 1 square foot of surface—that is, 1 square foot of supporting foliage. It is not always practicable to have the fruit just where it is wanted; it will suffice if one fruit be taken for every foot of trellis occupied, and if more fruit must be left upon a part of the tree to make up a deficiency in another it is desirable to apportion the extra fruit to a vigorous part of the tree; or in case of there being much fruit where the growths are weak, rather than weaken it still more by allowing a superfluity to make up the deficiency of other parts (and those frequently the strongest), thin the fruit to a foot distance apart, and let the other parts take care of themselves. The medium-sized Peaches may be left 9 inches apart. Some may consider the distance too great; my experience points the contrary. If there be one thing more than another to be guarded against in gardening it is that of too great expectancy in the capability of trees for producing fruit. Prodigious crops generally mean inferior quality.

Nectarines are small as compared with Peaches, and usually set more freely, nor are they thinned to anything like the same extent as Peaches. Such Nectarines as *Albert Victor* require to be thinned the same distance as the large-sized Peaches, and such sorts as *Elruge* ought to have 1 square foot of surface; none, however small, should have less than 81 square inches of supporting foliage surface, the fruit being 9 inches apart.

I would caution any with very vigorous trees from thinking that because the foliage is large twice as many fruit may be left upon them as on those less vigorous yet well furnished. Results do not justify such expectancy. Vigorous trees are frequently disappointing.

TRAINING.—When the shoots are 3 to 6 inches in length tying-in should commence, for if left until of greater length they cannot be brought into proper form. Either the shoot will snap off at its junction with its parent, or a very ungainly bend be formed. This work of tying the shoots ought to be done with care, leaving plenty of room for the swelling of the shoot. Care should also be taken in not having the tie very near the point of the shoot, or injury may result. All ties should be loose, the trees being often gone over for the regulation of the shoots. Nothing answers so well for tying either main branches or shoots as raffia or Chinese grass.

Some of the leaves will overhang the fruit, and where they do the fruit will be very highly coloured on the sun or exposed side, and very pale or not coloured at all beneath the leaves. The leaves in this case must be placed gently clear of the fruit when it takes the last swell after stoning, or even cutting away the parts overhanging the fruit. It is of more importance that the foliage have plenty of light and air than that the fruit be fully exposed to the sun.

MANURING.—Top-dressings are of importance. Nothing answers so well as fresh sheep droppings, giving the border a covering half an inch thick when the fruit is not much larger than a cob nut, or fresh cow dung answers nearly as well. It is surprising what a potency these stimulants have in bringing the roots to the surface, and the leaves by their deeper green soon show how they are being catered for. The effluvia given off is not pleasant to red spider. If the appearance of the manure is objected to it is easy to sprinkle it over with soil. Guano spread on the soil, just enough to yellow the surface, every time the border is watered I have found nearly as good as cow dung, &c.; but after the stoning a mulch of some kind is desirable, a covering 1 to 2 inches thick of short manure being valuable. Wood ashes are also a good application, but they are best applied at the dressing preparatory to forcing. Soot may be mentioned as very nearly equal to guano, and equally useful in the prevention of red spider. The surface may be made black at each watering, and the soot be washed in.

DISEASES.—Gumming is the most prevalent and arises from two causes—namely, too rich soil and damage to the branches and shoots. The first promotes long sappy growths which usually encumber to gum. It may be subdued by restraining the growth, which, however, is usually arrested as the border becomes solidified. The gumming consequent of too close tying suggests its own remedy, and bruising the shoots against the wires is equally inexcusable: in fact, nothing short of maltreatment will cause the gumming of forced Peach trees.

INSECTS.—The most insidious is the red spider (*Acarus telarius*). It is alleged that syringing prevents its attack. Experience tells nothing of the kind, for it we are very careful in applying the water without much force the red-coated fellow not only manages to maintain its footing but increases. The syringing must be thorough—the water driven with such force as to dislodge the enemy. It should, however, not be forgotten that a tree not duly attended to with water and otherwise ill fed at the roots is more liable to attacks of red spider than one well nourished both at the roots and at top by atmospheric moisture. When syringing cannot be done we must have recourse to the sulphur remedy. Sulphur commences to vaporise at a temperature of 165° to 170°. Upon an attack of red spider the pipes should be heated to a temperature hotter than the hand can bear and kept hot for at least six hours, being coated with sulphur brought to the consistency of thin paint, the house being closed. Gum water, 4 ozs. of gum arabic to a gallon of water, is best for mixing the sulphur. In the morning a thorough syringing may be given to the trees.

None of the insecticides are more fatal to red spider than softsoap solutions, 2 ozs. to a gallon of water, it being applied so as to thoroughly wet both the under as well as upper surface of the leaves. It is not, however, desirable to apply it after the fruit commences ripening.

Scale (*Coccus testudo*) is very troublesome and spreads rapidly, but, due regard having been paid to winter dressing, it does not make very great progress until the crop is ripe. Sometimes, however, it must be proceeded against. Six ounces of soft soap and a wineglassful of spirits of turpentine, mixed thoroughly, and added to three gallons of water at a tempera-

ture of 140°, applying with a syringe at a temperature of 120°, is the best remedy. This must not be applied until the leaves are full-sized and are firm in texture. Repeat if necessary.

Aphis, especially *A. persica*, takes greedily to the young wood, the flower, and tender leaves, and is as active in winter and spring as during the summer growth of the trees. It yields to fumigation with tobacco. To save fumigation the parts infested may be dressed with tobacco water—an effectual remedy, and upon its first appearance is easily applied with a brush; whereas if left the aphis spreads rapidly and will considerably disfigure the current growth, and is then not readily destroyed. Winter dressing of the trees with sulphur, &c., is a good preventive of this pest.

Thrips are best destroyed by fumigation, also the green aphis, which is not infrequent in cool houses.

Blisters do not prevail among forced Peach trees, but is common to trees against walls, being due to cold. Fungus is a result, not the cause of blister.

Mildew I have only once noticed in a forced Peach house, and that was upon the fruit of Early York. It succumbs to dusting with flowers of sulphur.—G. ABBEY.

DOUBLE PRIMULAS AT BURGHEY.

GLADLY DO I bear testimony to the excellence of the Primulas to which Mr. Gilbert alludes in page 189. They are indeed very fine—infinately superior to any others that I have seen. A saucer full of blooms sent me by Mr. Gilbert is beside me on my desk as I write. I literally feast my eye upon them. Ah! why did he not send cuttings? Tantalus! Tantalus! History repeats itself. Undoubtedly your longing for the hanging fruit closely resembled mine for the absent cuttings. A description of the blooms will best serve to explain why I thus covet my neighbour's possessions. In colour they range from a deep pink upwards to pure white, the gradations of shades being developed in the most charming manner, some being quite suffused with pink, others bearing most delicate tints and shades of the same colour upon a white ground, and others bearing innumerable spots and pencillings of pink. In size and form they are equally remarkable, many of them measuring nearly 2 inches in diameter, and all are as double as Daisies, but from their large size remind one more of a double *Petunia* than a *Daisy*. The petals are of great substance, large, beautifully fringed, and disposed in pleasing but by no means formal order, rising to a common centre, and imparting a full globular outline to the bloom. Who would not like to grow some? and who is there that does not sympathise with me in my longing for cuttings?—E. LUCKHURST.

ROYAL HORTICULTURAL SOCIETY.

HAVING reason to know from conversation with numerous amateurs and others that the lengthened correspondence which has recently appeared in the newspapers has tended only still further to mystify the public, and consequently to injure the Society even more than was previously the case, I venture to ask the favour of space in your paper that I may briefly draw attention to the following facts, hoping thereby to remove the doubts of many who will then be willing to come forward and aid by their subscriptions a Society which has done in the past, and is still doing, much valuable work.

1. The Society is now financially in a better position than it has been for several years past; but its income is still most inadequate, and with additional aid it would be better able to carry on its experiments and maintain the efficient working of those Committees whose labours have proved so beneficial to the general public.

2. Besides other valuable work, competitive trials of great scientific and practical value have for years been carried on, and are still being continued at Chiswick with the most excellent results, whilst the reports in the horticultural papers are a sufficient testimony to the thoroughly successful working of the Scientific, Fruit, and Floral Committees connected with the Society. The fortnightly flower shows are also a great success even beyond the most sanguine expectations.

3. What is now required is to obtain an increase of Fellows and members, and I think it cannot be too widely known that those who wish to join the Society can do so on the following terms:—

A. By payment of one guinea per annum, which payment entitles the member to use the gardens at all times, including all shows, fêtes, conservazioni, and promenades both at

Chiswick and at South Kensington, but without giving a vote at the meetings of the Society.

b. By payment of two guineas a-year, which entitles the Fellow to one yearly transferable ticket, admitting the bearer every day, and to all shows, fêtes, conversazioni, and promenades both at Chiswick and South Kensington, enabling him also to visit the shows at an earlier hour than the general public; entitling also the bearer with two friends to visit the gardens on all ordinary days, to receive forty orders giving free admission to promenades on all days except show and special days, and to have the right of voting at all meetings, besides other minor privileges.

c. By payment of four guineas a-year, which entitles the Fellow to two yearly tickets, both of which are transferable, and which give the bearers admission every day, and to all shows, fêtes, conversazioni, and promenades both at Chiswick and South Kensington, to visit the shows at an earlier hour than the general public, to receive forty orders giving free admission to promenades and all days excepting show and special day, the right of voting at all meetings, free admission to the reading-room, besides many other minor privileges.

d. *Bona fide* head gardeners on payment of 10s. 6d. per annum are admitted as members with the same privileges as those amateurs who pay one guinea per annum.

e. There is now no entrance fee, and anyone subscribing is in no way liable for any amount beyond the subscription for the year.

I am surely not too sanguine in expressing the hope that throughout Great Britain where the love of flowers is so universal, there are many who will be willing to come forward, and at so small a cost to themselves, to assist in supporting a Society which has done so much good in the past, and which I feel confident must with efficient aid have a very brilliant future. I venture to appeal on its behalf for such support, and shall gladly receive the names of any who are willing to become members, and I shall also be happy to obtain the necessary signatures to the nomination papers, so as to save as much trouble as possible as regards election, &c.—HARRY J. VEITCH, *Royal Exotic Nursery, Chelsea, S.W.*

NEW BOOK.

Cultivated Plants, their Propagation and Improvement. By F. W. BRIBDGE.

This is a trustworthy volume, for the author is a practical as well as scientific cultivator of plants. The first sentence in the preface is:—

“The late Dr. Lindley, when preparing the preface for his father’s ‘*Guide to the Orchard*,’ wrote the following:—‘There are two great considerations to which it is above all things necessary that the attention of the cultivator should be directed—namely, amelioration and propagation;’ and with this object in view the present handbook has been prepared.”

And the object has been well kept in view. Two brief extracts will enable our readers to judge of the contents of the work:—

“The known cases where the immediate action of foreign pollen on the fruit has been noted are so concisely given in Professor Dyer’s translation of Maximowicz’s paper cited above, that I gladly avail myself of the following quotation, which summarises the whole matter—with references to the original papers:—

“The few instances which may be found collected in Gaertner or Darwin. Thos. Maxx asserts that he observed different kinds of fruit on the Pear tree, of which a number of blossoms had been castrated, and, as he supposed, fertilised afterwards by neighbouring trees.

“Davis maintained that the fruit of Apples, Melons, and Maize underwent alteration in form, colour, and special qualities when they were planted near other kinds. Bradley even says that he had seen an Apple which was sweet on one side and sour on the other, and one half of which became soft when boiled, while the other remained hard. But these are only observations, and not experimental results. Wiegmann first obtained the latter in Pess. Gaertner tested experimentally many of the statements which we have quoted, and made experiments on other plants besides. He was only able, however, to confirm Wiegmann’s results to a certain extent. He is therefore disposed (and with much reason) to attribute the majority of such cases to variation in the individual; he allows, however, as a rare exception, the possibility of change even in the mother plant itself. Other observers (as, for example, Knight, and recently even Nägeli) deny even the possibility of such an influence.

“More recently Darwin has again quoted cases where, by crossing yellow and dark Maize, cobs were produced which con-

tained both yellow and dark grains. Hildebrand confirms these observations, and further cites the instance of an Apple which bore traces in its marking of the influence of another sort. But whilst the question has been in these cases only a variation in the colour, in the three which follow we find it affecting the form. Hildebrand has seen on Solanum edule (the well known Egg plant) a fruit which in colour, size, and shape exactly resembled a Tomato, and possessed only the greater dryness and firmness of the flesh of the Egg fruit, besides the smooth border of the seed, which in the Tomato is villous. Dr. Kanitz met with a case of a hybrid fruit between Lycopersicon esculentum and Capsicum annuum. Fritz Müller fertilised *Cattleya Leopoldi* by *Epidendrum cinnabarinum*, and obtained seeds of the former with the shape belonging to the latter. Meehan, lastly, observed that the bough of a Pear tree, which had always been altogether unfruitful, projected into the boughs of a neighbouring Apple tree. Fruits were produced which in skin, flesh, and other respects were altogether Apples, and had only the seeds, carpellary partitions, and stalk of the Pear.”

NOTES ON VILLA AND SUBURBAN GARDENING.

KITCHEN GARDEN.

The present is a capital time for making new beds for Asparagus, and the way to make them very much depends upon the position and nature of the soil as well as the time the beds are to remain, for, if the roots are to be taken-up in a few years for forcing, less trouble in preparing the soil suffices than when the beds are to remain till the plants are worn out. In consequence of frosty nights it is not advisable to rake-down the old beds too soon or too smoothly, but the surface may be loosened with the hoe, and the dressing-down will afterwards be easier done. The soil among growing crops should be loosened somewhat deeply, but not made very fine yet; the slight frosts will do the soil much good.

Take care that seedlings of Cauliflower, Lettuce, and Cabbage sown in frames are pricked-out in good time, as by leaving them too long they become leggy and are seldom afterwards so robust as if better treated. Carrots in frames ought to be thinned-out and plenty of air given to keep them dwarf. Those which are appearing outdoors should be protected from frost, and quicklime laid round the bed will keep slugs away, which might otherwise eat-off hundreds in a night. Lettuces which have been standing under the shelter of walls all the winter should be encouraged to grow by stirring the soil amongst them, and if they are too thick let some be taken away and planted in rich soil.

Parsley is a necessary article in all gardens, and to have good plants the seed should be sown early on a border; and then, if a piece of ground is prepared by deep digging and manuring, the best and most curled of the plants when large enough may be planted, and they get so well established during the autumn as to stand the winter well with the aid of a little protection, such as a slight framework covered with mats on frosty nights. Cauliflowers from hand-lights should be planted in well-prepared ground, the plants being carefully lifted with a trowel, with some earth attached to the roots. They should be planted 2 feet apart.

FLOWER GARDEN.
